## EXECUTIVE SUMMARY

During July 2007, a pilot recreational mark-selective fishery for Chinook salmon (Oncorhynchus tshawytscha, "Chinook") was implemented in Marine Catch Areas 9 and 10. This fishery represents the first experience using mark-selective regulations for Chinook in Marine Areas 9 and 10. The mark-selective regulations allow retention of adipose fin-clipped ("marked") hatchery Chinook salmon, while all "unmarked" Chinook must be released unharmed. Area 9 includes the marine waters inside and south of the Partridge Point - Point Wilson line, extending south and west of a line from Possession Point to Shipwreck, and north of the Apple Cove Point - Edwards Point line (Figure 1). Area 10 encompasses the marine waters extending south from the Apple Cove Point - Edwards Point line to a line projected true east-west through the north tip of Vashon Island (Figure 2).

The Areas 9 and 10 selective Chinook fishery began on July 16, 2007 with tremendous popularity among the angling public. This was the first time that Areas 9 and 10 were open for Chinook fishing during the summer since 1993, providing anglers a unique opportunity to catch Chinook salmon in the middle of an urban area. The selective Chinook fishery in Areas 9 and 10 was scheduled to begin on July 16, 2007 and continue through August 15 ( 31 days), or until the combined quota of 7,000 retained hatchery Chinook was attained (of which, only 1,700 Chinook could be harvested in Area 10), whichever occurred first. In total, the Area 9 selective Chinook fishery was open for 16 days, from July 16 through July 31. The Area 10 selective Chinook fishery was open for 13 days, from July 16 through July 28.

The pilot Chinook selective fishery in Areas 9 and 10 was patterned after the summer pilot Chinook selective fishery in Areas 5 and 6 (WDFW 2007b), which we have successfully conducted each summer season since 2003 in order to collect the data necessary to enable evaluation and planning of future mark-selective fisheries. The Areas 9 and 10 selective Chinook fishery was also patterned after the pilot seven-month winter selective Chinook fishery in Areas 8-1 and 8-2, which we have successfully conducted for two seasons, from October through April in 2005-06 and 2006-07 (WDFW 2007a and 2007c). The objectives of the Areas 9 and 10 pilot Chinook selective fishery were similar to the objectives of the Areas 5 and 6 pilot Chinook selective fishery and the Areas 8-1 and 8-2 selective Chinook fishery: 1) increase recreational fishing opportunity while meeting conservation goals for Puget Sound Chinook salmon defined by the Puget Sound Chinook Harvest Management Plan; and 2) collect information necessary to enable evaluation and planning of future potential Chinook markselective fisheries.

We implemented an intensive sampling design during the Chinook selective fishery in Areas 9 and 10 from July 16 through July 31, 2007. The study design consisted of comprehensive data collection strategies, including dockside sampling, on-the-water surveys, test fishing, and voluntary trip reports from charter boats and private (non-charter) boats, to obtain the critical data parameters needed to evaluate the selective fishery. Resulting data were used to estimate total salmon encounters and total effort, adipose mark rate by species, species composition of encounters, unmarked Chinook retention error, legal-size ( 22 inches or larger total length) versus sublegal-size (less than 22 inches) Chinook encounters, mortalities of retained and released Chinook, as well as mortalities of marked and unmarked double index tag (DIT) groups. Test fishing boats fished the entire proposed length of the fishery, from July 16 through August 15, in
order to collect information necessary to enable evaluation and planning of future potential Chinook mark-selective fisheries.

We contacted all known charter boat operators that fished in Areas 9 and 10 during the two-week fishery. During daily interviews, charter operators reported complete counts of salmon landed; further, based on private-fleet released:retained ratios, we estimated charter releases and combined these values with landings to quantify total charter encounters. Charter boats were ultimately treated separately and excluded from our creel survey estimates due to their high catch per unit of effort compared to private boats. We estimated total salmon encounters for private boats via the Murthy estimator method (Murthy 1957, Cochran 1977), incorporating dockside sampling and on-the-water surveys, while a complete census approach was used for charter boats.

In Area 9, for the period extending from July 16-31, we estimated via creel surveys that privateboat anglers retained a total of 4,938 Chinook (4,905 marked 33 unmarked or of undetermined mark status) in 18,160 angler trips, with an overall catch per unit of effort (CPUE) of 0.27 Chinook per angler trip. We also estimated that anglers released a total of 9,949 Chinook (2,070 marked, 3,465 unmarked, 3,353 unknown mark status, and 1,061 apportioned unidentified salmon). Thus, the total number of Chinook encountered (retained plus released) by private boats in Area 9 was estimated at 14,888 . In addition, thirteen charter boats fished in Area 9 during the month life of its fishery, and reported a total retained Chinook catch of 334 (all legal/marked). Additionally, we estimated that charters encountered and released 363 Chinook during their Area- 9 fishing activities. Adding charter and private-boat encounters together suggests that a total of 15,584 Chinook salmon were encountered by anglers in the Area- 9 selective fishery.

In Area 10, for the the period extending from July 16-28, we estimated via creel surveys that private-boat anglers retained a total of 1,507 Chinook ( 1,469 marked and 38 unmarked) in 8,374 angler trips, with an overall CPUE of 0.18 Chinook per angler trip. We also estimated that anglers released a total of 6,777 Chinook (1,066 marked, 1,225 unmarked, 2,561 unknown mark status, and 1,924 apportioned unidentified salmon). Thus, the total number of Chinook encountered (retained plus released) by private boats in Area 10 was estimated at 8,284. In addition, thirteen charter boat operators fished in Area 10 and reported landing a total of 70 legal-marked Chinook during their Area-10 activities. Charter releases were estimated at 107 ( 55 marked, 52 unmarked) for Area 10. Combining Chinook encounters due to charter activity $(177)$ to the estimated Chinook encounters for private boats $(8,284)$ resulted in a total estimate of 8,461 Chinook encounters (1,577 retained and 6,884 released) in Area 10 during its 13-day season.

Thus, for Areas 9 and 10 combined, we estimated a total of 24,045 Chinook encounters ( 6,850 retained and 17,195 released) during the fishery. More than $95 \%$ of this total estimate encounters was due to private-boat fishing activities.

The test boats in each area fished with downriggers over $94 \%$ of the time, reflecting the primary gear type used by the recreational fleet. The Area 9 test boat fished for a total of 137 hours during the fishery, while the Area 10 test boat fished for a total of 125 hours. Over the course of the fishery, the test boat in Area 9 encountered a total of 183 Chinook ( 141 legal and 42
sublegal), while the test boat in Area 10 encountered a total of 138 Chinook (39 legal and 99 sublegal). Based on the combined test fishing data from July 16 through August 15, 77\% of the Chinook encountered in Area 9 were legal-size, compared to $28 \%$ in Area 10. The adipose mark rate in Area 9 was $78 \%$ for legal-size Chinook and $83 \%$ for sublegal-size Chinook. In Area 10, the adipose mark rate was $72 \%$ for legal-size Chinook and $85 \%$ for sublegal-size Chinook.

A number of anglers who fished from private boats in Areas 9 and 10 submitted Voluntary Trip Reports (VTR's) containing information on each fish they encountered during the selective Chinook fishery. Participating anglers recorded a total of 163 Chinook encounters on VTR's for Areas 9 and 10 combined, of which 134 of the encounters ( $82 \%$ ) were from Area 9. Of these 134 Chinook, 80 ( $60 \%$ ) were legal-size, and $75 \%$ of these fish were marked. The 54 sublegalsize Chinook consisted of 31 marked and 23 unmarked ( $57 \%$ mark rate). A total of 29 Chinook encounters were recorded on VTR's in Area 10. Of these, 11 (38\%) were legal-size, and $73 \%$ were marked. The 18 sublegal-size Chinook reported in Area 10 consisted of 16 marked and 2 unmarked ( $89 \%$ mark rate).

Samplers recovered 255 coded-wire tags from Chinook harvested during the Chinook selective fishery in Areas 9 and 10. Of these, 253 were Puget Sound stocks and two were Canadian stocks. Fifty-four of these CWT recoveries were double index tags. Chinook from George Adams, Grovers Creek and Nisqually hatcheries contributed the highest number of double index tags. We estimated that anglers caught and released 290 legal-size, unmarked double index tagged Chinook, and that the mortality of unmarked legal-size double index tagged Chinook due to this selective fishery was 29 fish.

We compared two methods for estimating total legal-size and sublegal-size Chinook encountered during the fishery. The first method used the total number of Chinook encounters estimated from creel surveys and apportioned the encounters into the four categories of legal-size marked, legal-size unmarked, sublegal-size marked, and sublegal-size unmarked based on the proportions of these groups encountered during test fishing. Chinook encounters due to charter activities were added to private-boat counts to yield the total number of legal and sublegal Chinook encounters ( 24,045 total encounters: 15,584 in Area 9 and 8,461 in Area 10). Results of the "Method 1" estimation approach indicated that anglers released an estimated 5,571 legal-size and marked Chinook, or $32 \%$ of the fish they could have kept.

The second method for estimating the number of Chinook encounters was based on the assumption that anglers kept all Chinook that were legal-size and marked. For this method, total encounters were estimated by dividing the number of legal-size marked fish that anglers retained by the weighted proportion of legal-size marked fish from the test boats. The number of encounters in the remaining three categories was then obtained by multiplying the total encounters by the proportions for each corresponding category. Using this method, we estimated the total encounters at 13,770 Chinook. The true number of encounters thus likely lies between Method-1 and Method-2 estimates; i.e., between 13,770 and 24,405 Chinook encounters.

Using the "Method 1" approach of estimating encounters from the creel surveys and a release mortality rate of $15 \%$ for legal-size fish and $20 \%$ for sublegal-size fish, we estimated the total mortalities of Chinook in the selective fishery at 9,870 , of which $9 \%$ were unmarked. Using the encounters estimated by assuming anglers kept all legal fish ("Method 2") and a release mortality
rate of $15 \%$ for legal-size fish and $20 \%$ for sublegal-size size fish, we estimated total mortalities at 8,155 Chinook, of which $520(6 \%)$ were unmarked fish.

Although we believe the true number of mortalities lies between our two estimates, we used the higher number to compare estimated mortalities against pre-season predictions of mortalities. This approach resulted in total and class-specific estimates (i.e., by size/mark-status groups) that were similar to and generally below the predicted mortalities of 680 unmarked legal-size and 543 unmarked sublegal-size Chinook produced in the final pre-season run of the Fishery Regulation Assessment Model (FRAM; Model 3907), suggesting the Areas 9 and 10 selective Chinook fishery neither hindered nor jeopardized the 2007 conservation and management goals for Puget Sound Chinook.

Due to the new Chinook selective fishery in Areas 9 and 10 that included the regulation requiring anglers to release salmon without bringing the fish on board their vessel, we worked throughout the season to educate anglers about the proper methods of releasing fish and fish identification. Dockside samplers offered anglers a "dehooker" and a pamphlet describing selective fisheries, how to identify salmon species and their mark status, and how to use the dehooker.

Compliance with existing regulations, and the regulation prohibiting bringing unmarked salmon on board a vessel, was considered an integral part of a successful fishery. We estimated unmarked retention error (number of unmarked Chinook retained divided by total unmarked Chinook encounters) at <1\% in Area 9 and 2.5\% in Area 10.

In summary, the fishery was successful with respect to the objective of implementing monitoring and sampling programs to obtain management information for evaluation and planning of potential future selective Chinook fisheries. Estimated encounters were less than pre-season predictions. Compliance with fishing regulations was good during the fishery. The estimated number of mortalities of unmarked double index coded wire tagged fish was negligible.

## INTRODUCTION

In recent years, abundant runs of hatchery salmon have been mixed with depressed runs of wild salmon in the Northwest in both marine and freshwater environments. Providing opportunities to harvest abundant hatchery stocks while protecting wild stocks has been challenging. One tool for allowing harvest of abundant hatchery fish while limiting impacts on wild stocks is "selective fishing." In recreational selective fisheries, anglers are generally allowed to retain adipose fin clipped ("marked") hatchery fish and are required to release unclipped ("unmarked") fish. These unmarked fish are typically wild fish, but also include some unmarked hatchery fish.

While selective coho salmon (Oncorhynchus kisutch; "coho") fisheries have occurred in Oregon, Washington, and British Columbia at various times since 1998, and selective Chinook salmon (O. tshawytscha; "Chinook") fisheries have occurred in freshwater areas since 2000, a selective Chinook fishery had not been conducted in marine waters prior to 2003, when the first pilot summer Chinook selective fishery was initiated in Areas 5 and 6 (Thiesfeld and Hagen-Breaux 2005a). Each summer since 2003, we have successfully conducted the pilot Chinook selective fishery in Areas 5 and 6 to collect the data necessary to enable evaluation and planning of future mark-selective fisheries. Analyses of the selective Chinook fisheries in Areas 5 and 6 for the 2003 through 2006 seasons were presented in post-season reports (Thiesfeld and Hagen-Breaux, 2005a and 2005b; WDFW, 2005, 2006, and 2007b).

In addition, we have conducted the seven-month pilot selective Chinook fishery in Marine Catch Areas 8-1 and 8-2 for two seasons, from October 1 through April 30 during 2005-06 and 200607 , to collect the data necessary to enable evaluation and planning of future mark-selective fisheries. The Areas 8-1 and 8-2 pilot selective Chinook fishery represents the first experience using mark-selective regulations for Chinook in marine waters during the winter blackmouth fishery season. Anglers in Puget Sound commonly use the term "blackmouth" to indicate immature Chinook. Analyses of the first two seasons of data from this pilot seven-month winter selective Chinook fishery were presented in post-season reports (WDFW 2007a, 2007c).

The Areas 9 and 10 selective Chinook fishery began on July 16, 2007 with tremendous popularity among the angling public. This was the first time that Areas 9 and 10 were open for Chinook fishing during the summer since 1993, providing anglers a unique opportunity to catch Chinook salmon in the middle of an urban area. Area 9 includes the marine waters inside and south of the Partridge Point - Point Wilson line, extending south and west of a line from Possession Point to Shipwreck, and north of the Apple Cove Point - Edwards Point line (Figure 1). Area 10 encompasses the marine waters extending south from the Apple Cove Point Edwards Point line to a line projected true east-west through the north tip of Vashon Island (Figure 2).

Several marine area closures were in effect throughout the fishery in both Marine Areas 9 and 10, as follows: 1) the Hood Canal closure that included waters of Area 9 south of a line from Foulweather Bluff to Olele Point (Figure 1); 2) the Elliot Bay Closure which included waters of Elliot Bay east of a line from West Point to Alki Point, including the Duwamish Waterways upstream to the $1^{\text {st }}$ Ave South Bridge; and 3) the Sinclair Inlet Fishery Area including waters of Sinclair Inlet and Port Orchard south of the Manette Bridge in Bremerton, south of a line drawn true west from Battle Point, and west of a line drawn true south from Point White (Figure 2).

The selective Chinook fishery in Areas 9 and 10 was scheduled to begin on July 16, 2007 and continue through August 15 ( 31 days), or until the combined quota of 7,000 retained hatchery Chinook was attained (of which, only 1,700 Chinook could be harvested in Area 10), whichever occurred first. In total, the Area 9 selective Chinook fishery was open for 16 days, from July 16 through July 31. The Area 10 selective Chinook fishery was open for 13 days, from July 16 through July 28.

The Northwest Treaty Tribes and the Washington Department of Fish and Wildlife (WDFW) reached agreement to consider selective Chinook sport fishing in Areas 9 and 10 during the summer of 2007 as part of a pilot program for the purpose of collecting information necessary to enable evaluation and planning of future potential Chinook mark-selective fisheries. The pilot Chinook selective fishery in Areas 9 and 10 was patterned after the summer pilot Chinook selective fishery in Areas 5 and 6 (WDFW 2007b), which we have successfully conducted each summer season since 2003, as well as the pilot seven-month winter selective Chinook fishery in Areas 8-1 and 8-2, which we have successfully conducted for two seasons, from October through April in 2005-06 and 2006-07 (WDFW 2007a, 2007c).

The objectives of the Areas 9 and 10 pilot Chinook selective fishery were similar to the objectives of the Areas 5 and 6 pilot Chinook selective fishery and the Areas 8-1 and 8-2 pilot selective Chinook fishery: 1) increase recreational fishing opportunity while meeting conservation goals for Puget Sound Chinook salmon defined by the Puget Sound Chinook Harvest Management Plan; and 2) collect information necessary to enable evaluation and planning of future potential Chinook mark-selective fisheries. It was thought that a pilot summer selective fishery in Areas 9 and 10 that was limited in time and area would allow managers to determine the success of monitoring and sampling programs for collection of essential information.

Anglers were allowed to retain two marked (adipose fin-clipped) Chinook salmon $\geq 22 "$ ( 56 cm ) as part of their daily limit, and were required to immediately release, unharmed, any unmarked Chinook caught. Integral to the selective fishery was the regulation stating, "Any salmon to be released may not be brought on board a vessel". Due to the new selective fishery-related regulations in Areas 9 and 10, we educated anglers throughout the fishery about alternative methods for properly releasing fish, other than netting the fish and bringing fish into the boat. Dockside samplers offered anglers a "dehooker" and a pamphlet describing selective fisheries, how to identify salmon species, how to identify mark status of salmon, and how to use the dehooker. In addition to marked Chinook, anglers were also allowed to retain other salmon species (no minimum size) during the Chinook selective fishery period, under a total combined daily limit of two salmon.

This report presents the methods, post-season data analyses, and results generated from our intensive monitoring of the selective Chinook fishery in Areas 9 and 10 during July 2007 -- from July 16 through July 31 in Area 9 and from July 16 through July 28 in Area 10. Our study design consisted of comprehensive data collection strategies, including dockside sampling, on-the-water surveys, test fishing, and voluntary trip reports from charter boats and private boats, to obtain the critical data parameters needed to evaluate the selective fishery. Resulting data were used to estimate total salmon encounters and total effort, adipose mark rate by species, species composition of encounters, unmarked Chinook retention error, legal-size ( 22 inches or larger
total length) versus sublegal-size (less than 22 inches) Chinook encounters, mortalities of retained and released Chinook, as well as mortalities of marked and unmarked double index tag (DIT) groups.

Figure 1. Map of Marine Catch Area 9 in Puget Sound, where the selective Chinook fishery occurred from July 16 through July 31, 2007.

Figure 2. Map of Marine Catch Area 10 in Puget Sound, where the selective Chinook fishery occurred from July 16 through July 28, 2007.

## METHODS

An intensive sampling design was implemented in Areas 9 and 10 during the selective Chinook fishery period during July 2007 -- from July 16 through July 31 in Area 9 and from July 16 through July 28 in Area 10. The study design was based on Murthy's estimator (Murthy 1957, Cochran 1977) to obtain daily estimates of total catch and effort. The sampling design incorporated comprehensive data collection strategies consisting of dockside sampling, on-thewater surveys, test fishing, and voluntary trip reports from charter boats and private boats, as detailed below. Resulting data were used to estimate total salmon encounters and total effort, adipose mark rate by species, species composition of encounters, unmarked Chinook retention error, legal-size ( 22 inches or larger total length) versus sublegal-size Chinook encounters, mortalities of retained and released Chinook, as well as mortalities of marked and unmarked double index tag (DIT) groups.

## Dockside Sampling

Effort and catch were estimated by creel surveys generally following the procedures outlined in "Puget Sound salmon sport catch estimation study-1990" (Washington Department of Fisheries and Northwest Indian Fisheries Commission 1992), except that expansion factors were determined in-season, rather than using previously determined effort levels.

For each sampling day, six ramp samplers were stationed at selected sampled sites in Area 9, and four ramp samplers were stationed at selected sampled sites in Area 10. Samplers interviewed anglers as they exited the fishery from sampled sites, to collect data on angler effort, numbers of landed and released fish by species, and the adipose mark status of all Chinook and Coho encountered. In addition, all Chinook and Coho were electronically sampled to detect codedwire tag (CWT) presence. Snouts were collected from fish that detected positive for a CWT, and associated biological information was recorded (fork lengths, total lengths, and scale samples).

## Sampling Strata and Shifts

Sampling strata were divided into weekday (Monday through Thursday) and 'weekend' (Friday, Saturday, and Sunday) strata. Each week we randomly selected two days from the Monday through Thursday stratum for dockside sampling. In addition, we sampled every Friday, Saturday, and Sunday. Due to the exacting nature of a quota fishery, additional sampling days were added to ensure accurate catch accounting of the fishery to remain within the quota. Dockside sampling shifts lasted from approximately dawn until dark in order to intercept all boats.

## Sampled Sites

Sites to be sampled were selected as follows: Access sites in Areas 9 and 10 were divided into sampled and non-sampled sites. Access sites with low effort, as determined from boat survey data (see "Boat surveys" section below) were excluded in the sample. All anglers and fish exiting the fishery through the sampled sites were counted. Any boats that were missed at sampled sites were counted and recorded on the sampling forms.

In Areas 9 and 10, for each scheduled sampling day, two access sites (ramps or docks) were randomly selected for sampling based on a weighted random site selection process. A total of four shifts (an AM and PM in each area) were sampled per selected sampling day in each Area. A computer program developed by Mark Hino, WDFW Fish and Wildlife Biologist, was used to select the sampling sites based on their "size" or "weight" (i.e., the proportion of angler effort that on average uses the site; Murthy 1957, Cochran 1977). The computer application used a probability proportional to size without replacement cluster sampling scheme. The computer application required that the size measures of sampled sites in each Area sum to 1 ; thus, we used number of anglers from sampled sites to determine the adjusted size measures for these sites. The daily catch and effort estimates were expanded by an estimate of the proportion of effort that originated from these non-sampled access sites in each Area (see section below titled Estimated Catch and Effort), to compensate for leaving out the non-sampled sites from the sample frame at the time of site selection.

The sampled sites in Area 9 included the Port Townsend Boat Haven Ramp, Norton Street (Everett) Ramp, Kingston Public Ramp, Salsbury County Park Ramp, Mukilteo Lighthouse Park Ramp, and Fort Worden Ramp. The sampled sites in Area 10 included Armeni Public Ramp, Shilshole Public Ramp, and Kingston Public Ramp. The proportion of angler effort using these sampled sites, as compared to the non-sampled sites, is documented in the Results section below.

## Dockside Fishing Method Question

During dockside interviews, samplers recorded the predominant (based on time) angling method that was employed by the boat being interviewed, for the boats that successfully encountered Chinook. Responses were recorded on the sampling form according to the following five fishing method categories:

1. Weight \& Bait (W): Mooching or slow trolling with lead and herring/anchovy.
2. Downrigger Trolling (DR): Using either hardware or bait or any combination.
3. Jigging (J): Drifting, jerking pole up and down; for example using Buzz Bombs, Point Wilson Darts, or Crippled Herring.
4. Diver Trolling (DV): For example trolling with a Deep Six or a Pink Lady, using either hardware or bait or any combination.
5. Other (O): For example fly fishing, or trolling bucktails with or without weight.

We summarized the resulting information and instructed the test boat samplers on which method to employ in order to adequately represent the fishing methods used by the recreational fleet (see section below titled "Test Fishing").

## Boat Surveys

On-the-water surveys were used to estimate the percent of effort from sampled sites (versus nonsampled sites) and the proportion of angler effort at each sampled site. Boat surveys covered the entire area to pick up effort from all launch sites. We asked boat occupants where they intended to tie up or exit the fishery rather than where they launched. All boats that were actively fishing were contacted. We excluded non-fishing vessels and charter boats from the boat survey data. Charter boats were treated separately and excluded from our Murthy estimate due to their significantly higher CPUE compared to private boats, and because charter vessels were not necessarily exiting the fishery via our "sampled sites," which precluded sampling their catch (see "Charter Boats" section below).

In each area, we scheduled two boat surveys per week, one in the weekday stratum and one in the weekend stratum. In addition, boat surveys were conducted if anything changed in the fishery that could affect effort patterns (e.g., if launch sites open or close or if adjacent catch areas open or close). We calculated the size measures of Area 9 and Area 10 sites based on the most recently available boat survey data for weekend and weekday strata. Boat survey data were used to expand site estimates to all sites accessing the fishery and to provide in-season guidance to the dockside sampling site-selection process.

## Estimated Catch and Effort

## Private Anglers

The catch and effort (excluding charter vessels) observed at sampled sites was expanded to all access sites, based on their "size measure," to estimate total daily catch and effort in Areas 9 and 10. Sample data were combined and expanded to create stratum estimates of catch and effort with variances. We used a computer application developed in Microsoft Access by Kurt Reidinger, WDFW Fish and Wildlife Biologist, to enter the in-sample data, generate the expanded estimates, and produce the variances.

The formula for expanding catch and effort was:

$$
\hat{Y}=\frac{\left[\left(1-P_{2}\right) *\left(E_{1} / P_{1}\right)+\left(1-P_{1}\right) *\left(E_{2} / P_{2}\right)\right]}{\left(2-P_{1}-P_{2}\right)}
$$

where:
$\hat{Y}=$ daily estimator (e.g., anglers, marked Chinook retained, coho released, etc.),
$P=$ proportion of effort (size measure) at site 1 and 2 , and
$E=$ sampled (observed) estimator at site 1 and 2.
The formula for the variance of this estimator was:

$$
V(\hat{Y})=\frac{\left(1-P_{1}\right)\left(1-P_{2}\right)\left(1-P_{1}-P_{2}\right)}{\left(2-P_{1}-P_{2}\right)^{2}} *\left[\frac{E_{1}}{P_{1}}-\frac{E_{2}}{P_{2}}\right]^{2}
$$

If any boats were not interviewed during dockside sampling shifts, they were counted and recorded on the sampling forms. The average daily estimated catch for a given day and site was then multiplied by the observed number of missed boats, within the Microsoft Access estimation system, to estimate the unobserved catch. An analogous computation was made to account for the number of anglers not interviewed from the missed boats. These estimates, along with the count of missed boats, were added to the daily estimate totals at each site within the Access system.

For both Areas 9 and 10, the non-sampled sites were left out of the sample frame at the time of site selection, due to the draw-by-draw site selection process of the computer application that required the sum of the size measures of sampled sites to equal 1 . To compensate for this potential bias, the daily catch and effort estimates were expanded by an estimate of the proportion of effort that originated from the non-sampled access sites. The formula for this adjustment was as follows:

$$
\hat{Y}_{\text {adj }}=\frac{\hat{Y}}{\left(1-\hat{p}_{\text {nonsampled }}\right)}=\frac{\hat{Y}}{\hat{q}}
$$

where:

$$
\begin{aligned}
\hat{Y}_{a d j}= & \text { daily estimator after expansion by an estimate of the proportion of effort that } \\
& \text { originated from the non-sampled access sites, and } \\
\hat{q}= & \text { expansion factor to account for the proportion of effort originating from non- } \\
& \text { sampled sites. }
\end{aligned}
$$

The variance of the adjusted daily estimate was approximated by:

$$
V\left(\hat{Y}_{a d j}\right)=\hat{Y}_{a d j}^{2} *\left[\frac{\hat{V}(\hat{Y})}{\hat{Y}^{2}}+\frac{\hat{V}(\hat{q})}{\hat{q}^{2}}\right]
$$

Harvest and effort estimates were based on the following assumptions: 1) Boat surveys are unbiased estimates of the proportion of anglers accessing fisheries from non-sampled sites; 2) The proportion of total anglers accessing the fishery at site ' $A$ ' represents the proportion of total catch landed at site 'A'; 3) All anglers exiting at a sampled site are interviewed and all anglers accurately report their catch (if any boats are missed they are counted and catch and effort estimates are expanded appropriately); and 4) Catch per unit effort does not differ significantly between sampled and non-sampled sites.

Numbers of fish encountered but released during the Chinook selective fishery were also estimated based on dockside interviews of anglers, as part of the catch and effort sampling program. Anglers were asked to report numbers of fish released by species. In addition to Chinook, released species reported included coho salmon, pink salmon (O. gorbuscha), and unidentified salmon. Samplers logged fish in the unidentified salmon category when anglers reported releasing salmon that they were unable to identify (to species) at the time of encounter
(e.g., suspected "shakers" that were quickly released outside the gunwales, as per regulations). Dockside interview data were expanded to obtain total fishery estimates of released salmon, by species and mark-status category, using the same methods as described above for total catch and effort estimates.

As an additional estimation step towards quantifying total Chinook encounters, we apportioned a percentage of released, unidentified salmon to the total estimated number of released Chinook, based on the proportions of known salmon species released from creel surveys. Given that this quantity—apportioned unidentified salmon $\left(N_{\text {AUS }}\right)$ —is derived from estimated quantities [total unidentified salmon ( $N_{\mathrm{US}}$, from the Murthy estimator and subsequent adjustments described above), and the proportion of Chinook in estimated releases ( $p_{\text {Chin }}=N_{\text {Chin }} / \Sigma N_{\text {ID'd-salmon }}$ )], its estimator and variance are:

$$
\begin{gathered}
N_{\mathrm{AUS}}=N_{\mathrm{US}}{ }^{*} p_{\mathrm{Chin}} \\
V\left(N_{\mathrm{AUS}}\right)=V\left(N_{\mathrm{US}}\right)^{*} p_{\mathrm{Chin}}^{2}+N_{\mathrm{US}}^{2} * V\left(p_{\mathrm{Chin}}\right)+V\left(N_{\mathrm{US}}\right) * V\left(p_{\mathrm{Chin}}\right)
\end{gathered}
$$

where, also based on estimates:

## Charter Boats

After consulting with the WDFW biometrician, we elected to separate charter vessels from noncharter vessels (i.e., "private boats") in generating total catch estimates for Areas 9 and 10. Specifically, charter boats were treated separately and excluded from our Murthy estimate due to their high catch per unit of effort compared to private boats (i.e., to reduce potential bias and improve precision about estimates). In addition, charter boats often exited the fishery via sites outside of our sample frame and their landed catch was therefore not susceptible to sampling. Thus, while we relied on the Murthy estimator method to quantify total salmon encounters for private boats in Areas 9 and 10, a complete census approach was used for charter boats.

To encourage daily reporting and therefore facilitate a complete charter census, we contacted all licensed charter-boat operators planning to fish in the Areas 9 or 10 selective Chinook fishery during July 2007, prior to the season opening. In doing so, we established a protocol for daily reporting (via telephone or email) of catch, so that charter landings could be tracked and incorporated into WDFW's daily assessment of each fishery's progress relative to established quotas. Additionally, we instructed charter captains on the proper use of voluntary trip report (VTR) forms (e.g., data collection and recording techniques) at this time; VTRs (described in detail below) provide a means for gaining more detailed information on total effort and encounters resulting from charter activities.

Although charter-boat operators were highly cooperative in reporting their daily landings during the Areas 9 and 10 fisheries, a low return rate on charter VTRs (as of 28 September 2007) prevented us from gaining a complete census of charter releases. Given this, we had to estimate the number of Chinook encountered and released by charters in order to account for charter releases in our full fishery-impact evaluation. We estimated the number of Chinook released by
charter anglers based on stratum-specific released:retained ratios (i.e., marked and unmarked releases per legal-marked fish kept) estimated for private-fleet anglers. In doing so, we assumed that the identity and mark-status of all charter encounters would have been accurately determined (i.e., we did not estimate unknown mark-status releases or unidentified released salmon for charter anglers) and that private and charter retained:released ratios are generally equivalent.

## Test Fishing

We operated two test boats, one in Area 9 and the other in Area 10, for the month extending from July $16^{\text {th }}$ (the opening day of the two fisheries) to August $15^{\text {th }}$ (i.e., the last permitted day of the two fisheries if their respective quotas were not reached first). The crew on each boat consisted of two WDFW technicians per boat, fishing with one rod each. These test boat crews fished approximately five days per week (Monday through Friday) throughout the fishery.

Test-boat crews focused their fishing efforts at locations in Areas 9 and 10 that optimized their overall encounter rate (i.e., to increase precision) and mirrored choices made by the at-large private fleet. To better ensure the accuracy of test-fishing data, samplers fished for Chinook with similar methods and gear as did the recreational fleet. We prescribed the proportions of time that the test boats should spend fishing with different methods based on preceding dockside interview results. However, fishing methods were also adapted by test-boat crews in response to changing tides or other environmental conditions and due to observed changes in private-fleet behavior. At the end of each test-fishing day, the samplers summarized the amount of time they spent on fishing each method. In each area, the test-boat samplers fished predominately with downriggers (> $94 \%$ of the time), which was the predominant gear used by private anglers (see the Results section below).

For each test-boat hook-up, the encounter number, time sampled, species, mark status, and DNA vial number (if applicable) was recorded. Care was taken to handle all fish as gently as possible. Chinook were brought on board in a cotton mesh net and measured while still in the net. Samplers recorded the fork length, total length, and mark status for each Chinook on the scale card (legal-size Chinook were 22 inches and larger, while sublegal-size Chinook were less than 22 inches total length). Samplers collected three scales for each Chinook brought on board. Scales were collected following procedures outlined by the International North Pacific Fisheries Commission (1963), to enable age analysis of Chinook encountered in the fishery.

In addition, samplers used scissors to remove a $1-\mathrm{cm}^{2}$ section of tissue from the dorsal fin or the caudal fin of all Chinook brought on board, and then placed the sample in a solution of ethanol. Tissue samples were collected to obtain DNA for future genetic analysis of stock composition. All fish were released carefully and as soon as possible.

Data collected by the test boats were used to estimate species composition of encounters in the recreational fishery, the percent of fish encountered that were adipose fin-clipped (mark rate), and the proportions of Chinook that were legal-size versus sublegal-size. Test-fishing size/markstatus group (legal-marked, legal-unmarked, sublegal-marked, sublegal-unmarked) proportions were ultimately used to apportion private-fleet Chinook encounters to these same classes for use in fishery-impact estimation (Appendix A). In addition, Chinook size distributions were
contrasted between areas and mark-status groups (i.e., Area 9 vs. Area 10, and unmarked vs. marked lengths within areas) using two-tailed t-tests; significance was judged at $\alpha=0.05$.

To determine the age composition of the Chinook sampled by the test boats, we relied on the scale-reading expertise of John Sneva and Lance Campbell, Fish and Wildlife Biologists from WDFW, who analyzed all of the Chinook scale samples collected during the test fishery.

## Voluntary Trip Reports

Additional information on adipose mark rates and the percentage of Chinook that were legal-size (22 inches or larger total length) versus sublegal-size (less than 22 inches) was obtained from private-boat anglers who submitted Voluntary Trip Reports (VTR's) during the mark selective Chinook fishery in Areas 9 and 10 in July 2007. Participating anglers were asked to attend a class lasting from 30-45 minutes during which they received information on salmon species identification and became familiar with the VTR forms, what data to collect, how to fill out the forms, and how to turn in the forms.

On the VTR form, anglers were asked to record the date, number of anglers, target species, CRC Area, the species (if they positively identified the fish), including each Chinook or coho encountered, whether the fish was kept or released, total length to the nearest $1 / 8$ th inch, and whether the fish was adipose fin-clipped or not clipped. From this information, we estimated mark rates of legal and sublegal size Chinook and then compared these results with test-fishing data.

## Coded Wire Tagged Chinook Impacts

To determine the number of mortalities of unmarked coded-wire tagged Chinook resulting from the Chinook selective fishery, we analyzed recovered coded-wire tags and separated out tags from double index tag (DIT) groups. We then applied the methods described by WDFW (2002) to estimate the number of unmarked Chinook with coded-wire tags that would have been encountered, and applied a $10 \%$ selective fishing mortality rate $(\mathrm{sfm})$ to estimate the number of mortalities.

The analytical methods used to estimate unmarked mortalities in the selective fishery were developed by the Selective Fisheries Evaluation Committee - Analysis Work Group (SFECAWG 2002) and were evaluated by a workgroup consisting of State and Tribal biologists and statisticians, including members of SFEC-AWG (Joint Coho DIT Analysis Workgroup 2003). As indicated be SFEC-AWG, the goal of the analytical methods based on DIT groups is to estimate the number of unmarked mortalities in the selective fishery due to hook and release mortality. A key caveat with this approach is that the unmarked mortality estimate will be comparable to the number of landed marked mortalities and does not include adjustments for drop-off mortality or other types of mortality.

Thus, we used a selective fishery mortality rate (sfm) of $10 \%$ to estimate mortalities of the unmarked DIT fish encountered in the Areas 9 and 10 selective Chinook fishery, which is the sfm rate that is used in the Fishery Resource Assessment Model (FRAM) for legal-size Chinook. In addition, a drop-off mortality rate of $5 \%$ is added in FRAM, yielding a total sfm of $15 \%$ for
legal-size Chinook (Larrie Lavoy, WDFW, personal communication). We did not include the additional drop-off mortality rate of $5 \%$ for legal-size Chinook in the mortality analysis for unmarked DIT fish because the unmarked mortality estimate is comparable to the number of landed marked mortalities ( $M_{a, i}{ }^{M S F}$ in the equation below), determined from CWT's recovered at the dock, and drop-off mortality is not applicable to these retained Chinook.

Because the sampling rate changed throughout the fishery and among areas, we estimated encounters and mortalities for each recovered double index tag individually, and then summed the estimated mortalities for each hatchery and brood year. Variance and standard error were also estimated with methods described by WDFW (2002), and were estimated for individual tags, then summed for each hatchery and brood year.

The estimated number of unmarked mortalities was calculated by:

$$
\hat{U}_{a}{ }^{\text {MSF }}=\lambda^{R E L} \hat{M}_{a}{ }^{\text {MSF }}{ }_{s f m}
$$

with associated variance:

$$
\operatorname{Var}\left(\hat{U}_{a}^{M S F}\right) \approx\left(\lambda^{R E L}\right)^{2} s f m^{2} \hat{M}_{a}^{M S F} \frac{1-s}{s} .
$$

where:

$$
\begin{array}{ll}
s f m= & \text { selective fishing mortality rate, } \\
U_{a, i}{ }^{\text {MSF }}= & \text { aged } a \text { unmarked but tagged mortalities from stock } i \text { in the mark-selective } \\
& \quad \text { fishery, } \\
M_{a, i}{ }^{M S F}= & \text { aged } a \text { marked and tagged mortalities from stock } i \text { in the mark-selective fishery, } \\
s, & \text { sampling rate of the catch, } \\
\lambda^{R E L} \quad=\text { unmarked to marked ratio at release for fish in a DIT group, and } \\
\mathrm{V}(\hat{U})= & \text { variance of estimator } U .
\end{array}
$$

## Legal and Sublegal Chinook Encounters and Mortalities

We estimated season-total Chinook encounters by size and mark status [legal-marked (LM), sublegal-marked (SM), legal-unmarked (LU), and sublegal-unmarked (SU)] using two different approaches, "Method 1" and "Method 2". For each method, we applied the same approach towards estimating mortality from encounters (retention and release), even though each method was based on different initial estimates. In addition, both methods were applied to derive point estimates and variances on a stratum-by-stratum basis, and then these values were summed across the 13 - and 16 -day seasons to obtain totals. While we provide a summarized description of Methods 1 and 2 below, Appendix A presents a more detailed description of the analytical procedure applied for assessing total impacts generated by the Area 9 and 10 selective fisheries.

The first method for estimating Chinook encounters (Method 1) was based on an assumption that our dockside interview data (creel surveys) yield unbiased estimates of retained and released Chinook encountered by mark-status group. While the reliability of our estimate of Chinook
kept is likely high, whether or not anglers accurately report all Chinook encountered and released during their fishing trip(s) is less certain. In general, we assume the reliability of reported releases declines during periods of high encounters and that anglers generally over-estimate the number of fish released; thus, Method-1 estimates are likely biased high, if at all. Ultimately, size/mark-specific estimates were derived using a combination of creel survey encounter estimates (Appendix A), test-fishery proportions (for apportioning total encounters to the four size/mark status groups), and dockside size/mark-status observations (for apportioning kept Chinook-estimated by mark-status group only-to the classes LM, LU, SM, and SM).

The second method (Method 2) generated an estimate of total Chinook encounters based on the estimates of retained Chinook from creel surveys. Specifically, encounters were estimated by expanding stratum-specific estimates of legal-size and marked Chinook retained by the testfishery estimate of the proportion of legal-size marked fish in the at-large fishable population (i.e., Total Encounters = No. LM Chinook kept / LM proportion in the fishable population), and then were apportioned to class in the same manner as are Method-1 encounters. The accuracy of the Method 2 estimator thus depends on whether or not anglers retain all legal-marked Chinook encountered. If anglers sort their catch via releasing legal-size marked Chinook in hopes of catching a larger-size Chinook, we assume that Method-2 estimates will be biased low. Given that prior data from other Puget Sound selective Chinook fisheries indicate that anglers do release legal-size and marked Chinook on occasion (e.g., charter anglers typically release $<10 \%$; WDFW 2007a, 2007c), we believe that Method 2 provides a minimum estimate of Chinook encounters and mortality impacts due to the mark selective Chinook fishery in Areas 9 and 10.

We estimated total Chinook mortality resulting from the Areas 9 and 10 selective Chinook fishery, for each of the four size/mark status groups, by applying assumed mortality rates to LM, LU, SM, and SU retention and release estimates generated using Methods 1 and 2 above. For retained Chinook, the mortality estimate was equivalent to the total retention estimate for the applicable size/mark-status group. For released Chinook, we applied a mortality rate of $15 \%$ to legal-size marked and legal-size unmarked estimates and a mortality rate of $20 \%$ to sublegal-size marked and sublegal-size unmarked estimates. Similar to encounters, mortalities (and variances) were calculated for all categories on a stratum-by-stratum basis and then pooled across the seasons to estimate total Chinook mortalities.

In addition, total Chinook encounters and corresponding mortalities resulting from charter boat operations were incorporated into Method-1 and Method-2 estimates of encounters and mortalities. We added the reported Chinook encounters from charter vessels to the private-fleet estimates according to the appropriate retained/released and size/mark-status category. Appendix A presents the details of these and other estimation steps, as well as the equations for all estimators and their variances.

As a final step in our analysis, we compared observed season-total estimated Chinook encounters and mortalities for Areas 9 and 10 combined versus the pre-season modeled (FRAM Model 3907) number of Chinook encounters and mortalities, for each size and mark status category. Given that Method 1-based estimates likely provide a more conservative estimate of fishery impacts, we elected to use Method 1-based estimates of Chinook encounters and mortalities to compare with the modeled results.

Draft: 10/3/07

## RESULTS AND DISCUSSION

## Sampled Sites

Sites included in the Area-9 sample frame included: Dagmars Landing, Port Townsend Boat Haven Ramp, Norton Street (Everett) Ramp, Kingston Public Ramp, Salsbury County Park Ramp, Mukilteo Lighthouse Park Ramp, and Fort Worden Ramp. The sites actually sampled are shown in Table 1 and Appendix F. Sampled sites for the first week were determined prior to the fishery based on historical catch and effort data and current ramp effort knowledge of sampling supervisors.

The Area-10 sample frame included: Armeni Public Ramp, Brownsville Ramp, Edmonds Marina (Dry Storage), Kingston Public Ramp, Manchester Public Ramp, Port Orchard Ramp, and Shilshole Public Ramp. The sites actually sampled appear in Table 1 and Appendix F. Sampled sites for the first week were determined prior to the fishery based on historical catch and effort data.

## Boat Surveys

In Areas 9 and 10, we conducted a total of 4 boat surveys for each area during the fishery (Table 2). Boat surveys were used to estimate the percent of effort from sampled sites (versus nonsampled sites) and the proportion of angler effort at each access site.

We attempted to complete 1 weekday and 1 weekend boat survey in each area for each week that the fishery was open. Three weekday and one weekend boat surveys were conducted in Area 9 (Table 2). One weekend boat survey was canceled due to strong wind. Two weekday and two weekend surveys were conducted in Area 10 (Table 2). .

A summary of the boat survey data collected during the selective Chinook fishery in Areas 9 and 10 is presented in Tables 3 and 4 (all boat surveys combined). In Area 9, we surveyed a total of 577 boats and 1185 anglers over the fishery. Of these anglers, $49 \%$ exited the fishery via sampled sites. In Area 10, we surveyed a total of 423 boats and 815 anglers over the fishery. Of these anglers, $59 \%$ exited the Area 10 fishery via sampled sites.

## Size Measures of Sampled Sites

The sites that were randomly selected for sampling in Areas 9 and 10, and the size measures determined for each site based on the boat survey data, are listed in Appendix F. Over the fishery, Norton St (Everett) Ramp dominated as the site with the highest overall size measure in Area 9, with a total size measure of 0.441 weekday and 0.515 weekend (adjusted size measure; Tables 3A and 3B). Shilshole Public Ramp dominated as the site with the highest size measure in Area 10, with a total weight of 0.375 weekday and 0.355 weekend over the 13-day fishery (adjusted size measure).

Table 1. List of 'sampled sites' for Areas 9 and 10, showing the number of days sampled per month per site and the proportion of total time that each site was sampled during the selective Chinook fishery from July 16-31, 2007 (28 ${ }^{\text {th }}$ Area 10).

## Estimates of Catch and Effort: Private Boats

## Area 9

For private boats fishing in Area 9 during the summer selective Chinook fishery, we estimated that a total of 4,938 Chinook ( 4,905 marked, 28 unmarked, and 5 of undetermined mark status) were retained in 18,160 angler trips (Table 5). We estimated that anglers released a total of 8,888 Chinook ( 2,070 marked, 3,465 unmarked, and 3,353 unknown mark status) (Table 5). In addition, given the estimate of 1,160 released salmon of unknown species (i.e., 'Unk. Salmon' in Table 5) and stratum-specific proportions of Chinook salmon among positively identified salmon releases [\% Chinook mean: 88.5\%, (SD: 13.1\%)], we apportioned 1,061 additional fish to the released Chinook category for total fishery-impact estimation. Thus, the total number of Chinook encountered (retained plus released, inclusive of apportioned unidentified salmon) by private boats in Area 9 during the 16-day fishery was estimated at 14,887 . In addition to Chinook, anglers kept an estimated 709 coho ( 501 marked and 208 unmarked) and 50 pink salmon; an estimated 1,138 coho (296 marked, 328 unmarked, and 513 unknown mark status) and 50 pink salmon were also encountered and released.

## Area 10

For private boats fishing in Area 10 during the summer selective fishery, we estimated that a total of 1,507 Chinook ( 1,469 marked and 38 unmarked) were retained in 8,374 angler trips (Table 6). We estimated that anglers released a total of 4,852 Chinook (1,066 marked, 1,225 unmarked, and 2,561 unknown mark status) (Table 6). In addition, given the estimate of 2,194 released salmon of unknown species (i.e., 'Unk. Salmon' in Table 6) and the stratumspecific proportions of Chinook salmon among positively identified salmon releases [ $\%$ Chinook mean: 89.4\%, (SD: 4.3\%)], we apportioned 1,924 additional fish to the released Chinook category for total fishery-impact estimation. Thus, the total number of Chinook encountered (retained plus released, inclusive of apportioned unidentified salmon) by private boats in Area 10 during the 13-day fishery was estimated at 8,284 . Also, we estimated that anglers retained 831 coho ( 530 marked and 301 unmarked) and 44 pink salmon. Total estimates of non-Chinook salmon releases for the 13-day fishery included 647 coho (124 marked, 118 unmarked, and 406 unknown mark status), and 17 pink salmon (Table 6).

Table 5. Estimates of salmon catch and effort for private boats in Marine Area 9 with standard errors, based on dockside angler interviews during the Chinook Selective Fishery from July 16-31, 2007. Values may not add exactly due to rounding error.

## Angler Effort Trends

Angler effort in areas 9 and 10 was high overall and persistent across all sampled days for the respective 16- and 13-day selective-harvest Chinook seasons. In total, 26,534 angler trips ( 18,160 in 9 and 8,374 in 10) and 12,665 boat trips ( 8,525 in 9 and 4,140 in 10) were made in order to pursue Chinook salmon in the Areas 9 and 10 fisheries. Daily Murthy estimates indicate that anglers: 1) made nearly 2,000 trips per day in areas 9 and 10 combined, on average; 2) expended more effort on weekends than weekdays (Area 9: 1,549 angler trips per day on weekend and 819 on weekdays; Area 10: 909 and 487, respectively); and 3) fished more intensively in Area 9 than 10 (18,160 vs. 8,374 total angler trips). Temporal trends in angler effort for days when dockside sampling occurred during the two selective-fishery seasons are presented in Figures 3 (Area 9) and 4 (Area 10).

## Catch per Unit of Effort (CPUE)

## Area 9

For private boats fishing in Area 9, anglers kept 0.27 Chinook salmon per trip on average (i.e., based on season-total catch and effort). Daily CPUE was high ( 0.47 Chinook kept per angler) at the open of the fishery and then dropped off quickly during the first open weekend, after which it hovered around 0.20 Chinook per angler for the second two thirds of the season (Figure 5).

## Area 10

Area-10 anglers experienced somewhat lower catch rates than Area-9 anglers, with a seasonwide CPUE of 0.18 Chinook retained per angler trip (Figure 6). In contrast to Area 9, however, catch rates were relatively low for the first week of the fishery (average CPUE for the 4 days sampled during the first week: 0.13 Chinook per angler trip) and relatively high on its closing day (the maximum catch rate, 0.27 Chinook per angler trip, was observed on the second-to-last day of the fishery). Thus, the general temporal CPUE pattern for Area 10 was one of low initial catch rates rising towards a peak near the July $28^{\text {th }}$ close of the fishery.

Draft: 10/3/07

## Estimated Chinook Encounters: Private Boats

## Area 9

Based on the days sampled in the Area-9 fishery, private boats retained an estimated average of 278 Chinook per day over the 16 days of the fishery (Figure 7). The daily catch of Chinook peaked on the first day of the fishery (based on sampled days only), with an estimated 636 Chinook retained; daily catch then declined continuously until it reached its minimum ( 71 Chinook retained) on the second-to-last day of the fishery (Table 7A).
Daily Chinook encounters (retained plus released, inclusive of apportioned unidentified releases) also peaked on the first day of the fishery; we estimated that 1,629 Chinook were encountered ( 686 retained and 943 released) at this time. In contrast to Chinook retention, which exhibited a monotonic decline after an initial peak, a second total-encounters peak occurred during the second weekend of the fishery. The second peak was driven primarily by in increase in the number of Chinook salmon released per day (Figure 7). Overall, the mean daily Chinook encounter estimate (for days sampled only) for the Area 9 season was 885 (278 retained and 607 released).

## Area 10

For days sampled in Area 10, private boats retained an estimated average of 125 Chinook per day over the 13 days of its selective-harvest season. In contrast to Area 9, where catch estimates were higher overall and declined across the duration of the fishery, daily Chinook landings increased continuously from the start to the close of the Area-10 fishery (Figure 8; Table 7B); daily catch was low initially ( 77 Chinook retained per day on average for the first week) and then rose to a season peak on the last day of the fishery ( 28 July; 373 Chinook total retained). The temporal trend in daily total encounters (retained plus released, inclusive of apportioned unidentified releases) mirrored that of total catch (Figure 8) - the maximum estimate of daily encounters also occurred on the $28^{\text {th }}$ of July, with anglers encountering a total of 2,232 ( 373 retained and 1,859 released) Chinook salmon on that day. The seasonwide mean daily encounter estimate for sampled days was 709 Chinook ( 125 retained and 584 released).

## Combined Areas

For Areas 9 and 10 combined, private boats retained a total of 6,446 Chinook during the $\sim 2$ week long selective Chinook season. Of this total, 6,375 were marked and 71 were unmarked (Tables 7A and 7B). Private anglers released a total of 16,725 Chinook during the course of the fishery in the combined areas, and the released-to-retained ratio averaged 1.21 ( 0.49 for marked-only-releases and 0.73 for unmarked releases) for known mark-status and definitively identified salmon. Thus, the total number of Chinook encountered (retained plus released, inclusive of apportioned unidentified salmon releases) was estimated at 23,171 (14,887 in Area 9 and 8,283 in Area 10) (Tables 7A, 7B, and 8). Further, creel-survey estimates indicated that that $66.6 \%$ of the Chinook encountered (legal + sublegal) in Area 9 and $66.7 \%$ in Area 10 were marked (e.g., Table 8). The observed (in-sample) data collected during dockside angler interviews, which were used to generate the total estimates, are presented by stratum in Appendices C and D.

## Charter Boats: Chinook Encounters

Thirteen charter-boat operators reported taking clients fishing in areas 9 and 10 during their respective selective seasons. Based on 113 charter trips made ( 79 in Area 9 and 33 in Area 10), charter captains reported landing a total catch of 404 Chinook salmon ( 334 in 9 and 70 in 10) and experienced a CPUE of 3.6 Chinook per charter trip on average (4.2 in Area 9, 2.1 in Area 10). Considering charter and private-fleet landings in combination, charter catch approximated $5 \%$ ( $4.5 \%$ in Area 9 and $6.4 \%$ in Area 10) of the total marked-Chinook landings for the Areas 9 and 10 selective fisheries (Table 8).

Due to logistic constraints, we did not obtain a complete census of Chinook salmon releases resulting from charter-boat operations in either area 9 or 10 . In order to account for charter releases in total fishery-impact estimation, we estimated these values for marked and unmarked groups on a stratum-by-stratum basis using private-fleet retained:released ratios for both of these classes of fish. Given this approach, we estimated that charter boats encountered and released 132 marked and 230 unmarked Chinook in Area 9 and 55 marked and 52 unmarked Chinook in Area 10 during the course of the Areas 9 and 10 selective fishery. Thus, charter boat operations resulted in a total of 873 (696 in Area 9, 177 in Area 10) Chinook encounters (retained + released). Stratum-specific censused-catch and estimated-release values for charter-boat operations in areas 9 and 10 appear in Tables 7A and 7B.

## Total Chinook Encounters: Areas 9 and 10 Combined

In Area 9, adding encounters for private boats $(14,887)$ to charter encounters $(697)$ resulted in an estimated total of 15,584 ( 5,272 retained, 10,311 released) Chinook encounters for this 16-day fishery (Tables 7A and 8). 95.5, 93.7, and $96.5 \%$ of the Chinook encounter, retention, and release totals accounted for within the fishery were due to private-fleet activity.

Based on the combination of Chinook encounters for private boats $(8,284)$ and charter boats (177), we estimated that anglers fishing in Area 10 encountered a total of 8,461 (1,577 retained, 6,884 released) during this 13-day fishery (Tables 7B and 8). Similar to Area 9, private-fleet activities generated $\sim 95 \%$ (total, retained, and released) of Area 10 selective-fishery impact.

Based on the combination of marine-area estimates, a total of 6,850 Chinook salmon were retained and 17,195 released (inclusive of apportioned, unidentified salmon releases) by anglers fishing in areas 9 and 10 between 16 and 31 July. Thus, an estimated total of 24,045 Chinook salmon were encountered by anglers overall.

Figure 7. Daily Chinook retention and release (inclusive of apportioned unidentified salmon releases) estimates for private boats sampled in Marine Area 9 during the Chinook selective fishery from July 16-31, 2007.

Figure 8. Daily Chinook retention and release (inclusive of apportioned unidentified salmon releases) estimates for private boats sampled in Marine Area 10 during the Chinook selective fishery from July 16-28, 2007.

## Dockside Length Analysis

In Area 9, dockside samplers collected a total of 568 length samples from retained Chinook (559 ad-marked, 8 unmarked, and 1 undefined mark status) during the 16 -day selective Chinook fishery (Table 9). Four of the unmarked Chinook and the one fish with an undefined mark status were legal-size Chinook. Of the 559 ad-marked retained Chinook, 541 were legal-size and 18 were sublegal-size. Thus, $3.2 \%$ of the length samples collected from retained ad-marked Chinook in Area 9 were sublegal size (Figure 9). The average size of the 18 marked sublegalsize Chinook was 52.7 cm total length.

In Area 10, dockside samplers collected a total of 374 length samples from retained Chinook ( 366 ad-marked, 8 unmarked, and 0 undefined mark status) during the 12 - day selective Chinook fishery (Table 9). 7 of the unmarked Chinook were legal-size fish. Of the 366 admarked retained Chinook, 344 were legal-size and 22 were sublegal-size. Thus, $6.4 \%$ of the length samples collected from retained ad-marked Chinook in Area 10 were sublegal size (Figure 9). The average size of the 22 marked sublegal-size Chinook was 50.6 cm total length. For Areas 9 and 10 combined, a total of 925 ad-marked retained Chinook were sampled, of which 885 were legal-size and 40 were sublegal-size (Table 9). Thus, $4.3 \%$ of the length samples were from sublegal-size Chinook for the two areas combined (Figure 9). The average size of the 40 retained sublegal-size Chinook was 51.7 cm total length, approximately 3.8 cm under the legal size limit ( 55.8 cm ).

Table 9. Summary of length samples collected from retained Chinook during dockside angler interviews in the Areas 9 and 10 selective Chinook fishery from July 16 - 31, 2007

| Area | Mark Type | Number Sampled |  |  |

## Dockside Fishing Method Question

For the duration of the fishery, we recorded a total of 1,663 responses to the fishing method question for private boats that successfully encountered Chinook (1156 boats in Area 9 and 507 boats in Area 10). Of these, 1,663 boats ( $90.4 \%$ ) used downriggers as the predominant fishing method (Table 10). In Area 9, 1,040 (91.3\%) boats reported that downriggers were used as their predominant fishing method, while $65(5.6 \%)$ boats employed the weight and bait method, 44 $(2.5 \%)$ boats used the diver method, $6(0.5 \%)$ used the jigging method and $1(0.1 \%)$ boat used an "other" fishing method (trolling without downriggers). In Area 10, 436 (87.1\%) boats reported that downriggers were used as their predominant fishing method, while $56(10.7 \%)$ boats employed the weight and bait method, $13(2.0 \%)$ boats used the diver method, $2(0.3 \%)$ used the jigging method (Table 10).

## Test Fishing

## Gear Types and Fishing Time

The test boats in Areas 9 and 10 attempted to replicate the fishing methods that anglers used to encounter Chinook by employing fishing methods in the same proportions reported by anglers. Anglers predominantly used downriggers to encounter Chinook in both areas $(91 \%$ of boats in Area 9 and $87 \%$ of boats in Area 10; Table 10); therefore, the test boats employed downriggers for over $94 \%$ of the test fishing time during the season (Table 11).

The Area 9 test boat fished with downriggers $88 \%$ of the time, totaling 66 hours and 26 minutes while the fishery was open (July 16-31) and 115 hours and 22 minutes total during their monthlong sampling effort (July 16-August 15). In addition the Area 9 test boat fished the weight and bait method for 8 hours and 36 minutes while the fishery was open and 22 hours and 12 minutes over the one-month fishery (Table 12).

The Area 10 test boat fished with downriggers $95 \%$ of the time totaling 60 hours and 9 minutes while the fishery was open (July 16-28) and 119 hours and 18 minutes total during their monthlong sampling effort (July 16-August 15). In addition, the Area 10 boat fished with the 'weight and bait' method for 4 hours and 51 minutes, and the 'jigging' method for 1 hour and 2 minutes (Table 12).

The Area 9 test boat averaged 27 hours and 30 minutes of fishing time per week and fished a total of 23 days out of a possible 23 days. The Area 10 test boat fished an average of 25 hours and 2 minutes per week and fished for 22 out of the possible 23 days (Table 12).

## Chinook Encounters and Mark Rates

For the one-month duration of the fishery, the test boat in Area 9 encountered a total of 183 Chinook ( 141 legal and 42 sublegal), while the test boat in Area 10 encountered a total of 138 Chinook ( 39 legal and 99 sublegal). Test boat catches during the fishery showed that $77 \%$ of the Chinook encountered in Area 9 were legal-size, compared to $28 \%$ in Area 10 (Table 13). Based on the combined test fishing data, the adipose mark rate in Area 9 was $78 \%$ for legal-size

Chinook and $83 \%$ for sublegal-size Chinook. In Area 10, the adipose mark rate was $72 \%$ for legal-size Chinook and $85 \%$ for sublegal-size Chinook (Tables 13 through 15).

In Area 9, the season-total catch composition for the four size/mark-status categories was: $60.1 \%$ legal and marked; $16.9 \%$ legal and unmarked; $19.1 \%$ sublegal and marked; and $3.8 \%$ sublegal and unmarked (Table 14). In Area 10, the season-total rates in the four categories were: $20.3 \%$ legal and marked; $8.0 \%$ legal and unmarked; $60.9 \%$ sublegal and marked; and $10.9 \%$ sublegal and unmarked (Table 15).

## Chinook Size and Age

Analysis of Chinook total lengths collected by the test boat samplers for the fishery indicated a higher frequency of sublegal-size Chinook in the Area 10 test fishery compared to that in Area 9 (Figures 11 and 12). The average size of Chinook in Area 9 was 66.6 cm total length, with a minimum of 33.1 cm and a maximum of $94.2 \mathrm{~cm}(\mathrm{n}=183)$. The mean size of Chinook in Area 10 was 14 cm lower, averaging 52.5 cm total length, with a minimum of 29.9 cm and a maximum of $89.0 \mathrm{~cm}(\mathrm{n}=138)$. A two-tailed t -test indicated that this difference was statistically significant $\left(P<0.001, \mathrm{t}_{0.05(2)}=-9.33\right.$, d.f. $\left.=319\right)$. Furthermore, the percent of fish caught by the test boats that were legal-size was higher in Area 9 (77\%) compared to Area 10 (28\%).

In both areas, unmarked Chinook tended to be slightly larger than marked Chinook on average (5 cm in Area 9 and 4 cm in Area 10) (Figures 11 and 12). This difference was statistically significant for Area $9\left(P=0.0346, \mathrm{t}_{0.05(2)}=-2.13\right.$, d.f. $\left.=181\right)$ but not Area $10\left(P=0.183, \mathrm{t}_{0.05(2)}=\right.$ -1.34 , d.f. $=136$ ). In general, however, marked Chinook constituted the majority of total encounters across all $5-\mathrm{cm}$ size-classes examined.

Analysis of scale samples showed that the test boats in Areas 9 and 10 caught Chinook from brood years 2003, 2004, and 2005 (age 4, 3, and 2, respectively) (Figures 13 and 14). In Area 9, the average total length of the 2003-2005 brood samples was $82.6,68.8$, and 49.5 with sample sizes of $n=30$, 91 and 47 respectively (Figure 13). In Area 10, the average total length of 20032005 brood samples was $81.8,71.8$, and 44.9 with sample sizes of $n=8,27$, and 100 respectively (Figure 14). The difference between total test-boat Chinook encounters and aged individuals was due to a limited number of unreadable scale samples (area 9: 15 samples not aged; area 10: 3 samples not aged).

## Other Species

In addition to Chinook, the test boat in Area 9 caught and released 13 coho (Oncorhynchus kisutch), 2 pinks (O. gorbuscha), 1 chum ( $O$. keta), 2 butter sole (Isopsetta isolepsis), 5 rock sole (Lepidopsetta bilineata), 1 arrowtooth flounder (Atheresthes stomias), 107 spiny dogfish (Squalus acanthias), and 18 Pacific sandab (Citharichthys sordidus). The test boat in Area 10 caught and released 37 coho, 1 pink, 2 lingcod (Ophiodon elongatus), 62 Pacific sandab, 22 spiny dogfish, 2 copper rockfish (Sebastes caurinus), 2 brown rockfish (S. auriculatus), and 1 red Irish lord (Hemilepidotus hemilepidotus) (Table 16).

## Voluntary Trip Reports (VTR's)

Anglers fishing from private vessels in Area 9 returned Voluntary Trip Reports (VTR's) at a moderate rate, with 39 VTR's returned over the 16 day fishery, while anglers in Area 10 returned a total of 13 VTR's. In Area 9, a total of 134 Chinook encounters were recorded on VTR's over the 16-day fishery (Table 17). There were 80 legal-size encounters recorded on VTR's for Area 9. Of those encounters 60 were marked, and 20 were unmarked ( $75 \%$ mark rate) Of the 54 sublegal size encounters 31 were marked and 23 were unmarked ( $57 \%$ mark rate) (Table 19).

In Area 10, a total of 29 Chinook were recorded on VTR's (Table 18). Eleven of the Chinook (38\%) recorded on VTR's in Area 10 were legal-size, and $73 \%$ of these fish were marked (Table 19). Of the 18 sublegal-size Chinook reported in Area 10, 16 were marked and 2 were unmarked ( $89 \%$ mark rate), resulting in an overall combined mark rate of $83 \%$ for the 29 Chinook reported on VTR's (Table 19).

## Comparison of Mark Rates: Test Fishery vs VTR's

We calculated the mark rates of legal-size Chinook encountered in Area 9 from VTR's submitted by private-boat anglers and compared these results with equivalent data from the test boat in Area 9. The Area 9 VTR's showed variable mark rates for legal-size Chinook encounters compared to the mark rates for the test boat in Area 9 (Figure 15). This variability in the VTR mark rates, however, is likely the result of low sample sizes for legal Chinook reported on VTR's relative to those obtained by the test boat (Figure 15). Similarly, a comparison of VTR- and test boat-based mark rates between Areas 9 and 10 suggests the former was less variable than the latter. This difference, however, was also likely due to sampling error (i.e., small sample sizes were obtained in Area 10) (Figure 15). When comparing overall mark rates for the duration of the fishery, mark rates appear to be consistently above average. For statistical weeks 29 and 30 the legal-size mark rate for the test boat in Area 9 was $82 \%$ while the mark rate from VTR's was
$75 \%$. In Area 10 the legal-size mark rate for the test boat was $76 \%$ while the mark rate from VTR's was 72\%.

## Coded Wire Tags

Samplers recovered 255 (179 Area 9 and 76 Area 10) coded-wire tags from Chinook harvested during the 16-day Chinook selective fishery in Areas 9 and 10 (Table 20; Appendix D). Of these, 253 were Puget Sound stocks, and two were Canadian stocks. Fifty-four of these CWT recoveries were double index tags (Tables 20 and 21). Chinook from George Adams, Grovers Creek and Nisqually hatcheries contributed the highest number of double index tags. We estimated that anglers caught and released 290 (218 in Area 9 and 72 in Area 10) legal-size, unmarked double index tagged Chinook, and that the mortality of unmarked legal-size double index tagged Chinook due to this selective fishery was 29 fish ( 22 Area 9 and 7 Area 10) (Tables 21A and 21B).

Figure 15. Fishery mark rate (\% adipose fin-clipped) of legal-size Chinook salmon caught in Areas 9 and 10 by the test boat, compared with mark rates from private-boat anglers reporting their catch on Voluntary Trip Reports (VTR's), from July 16 - 31, 2007. Sample sizes for the test boat are in curved brackets $\}$, while sample sizes for VTR's from private boats are in parentheses ().

Table 20. Summary of total observed (in-sample) coded-wire tag recoveries from Chinook salmon harvested during the Chinook selective fishery in Areas 9 (July 16-31) and 10 (July 16-28).

## Encounters and Total Mortalities

## Method 1 Results

Based on Method 1, we estimated a total of 24,045 Chinook encounters in Areas 9 and 10 (15,584 in Area 9 and 8,461 in Area 10). These Chinook encounters consisted of 6,582 retained legal-size fish ( 6,532 marked and 50 unmarked), 8,372 released legal-size fish (5,571 marked and 2,801 unmarked), 267 retained sublegal-size fish ( 246 marked and 21 unmarked), and 8,823 sublegal-size released fish ( 7,034 marked and 1,789 unmarked) (Table 22; Table 24).

The estimate of 5,571 released legal-size and marked Chinook (5,081 in Area 9 and 1,451 in Area 10) suggests that anglers released $46 \%$ of the legal-size and marked Chinook they could have kept. While we believe that some "high grading" of catch occurred during the course of the fishery given the moderate catch rates estimated for Areas 9 and 10 (CPUE: 0.27 and 0.18 Chinook kept per angler trip, respectively), we believe that anglers would have retained a higher proportion of encountered, legally harvestable fish than this suggests. Thus, we suspect the calculated release rate of $46 \%$ for legal-size marked fish (and by implication our "Method-1" estimate of total encounters) is probably biased high.

Based on the estimates of encounters produced using Method 1, we estimated the total Chinook mortality during this fishery at 9,870 fish (Table 22; Table 25) of which $91 \%$ were marked. Estimated mortalities for both areas combined consisted of 6,582 retained legal-size fish (6,532 marked and 50 unmarked), 1,256 released legal-size Chinook ( 836 marked and 420 unmarked), 267 retained sub-legal fish ( 246 marked, 21 unmarked), and 1,765 sublegal released fish (1,407 marked and 358 unmarked).

## Method 2 Results

Using Method 2, we estimated that anglers encountered a total of 13,770 Chinook salmon in Areas 9 and 10 during their respective fisheries (Table 23). The 13,770 total encounters consisted of 6,582 retained legal-size fish (6,532 marked and 50 unmarked), 1,580 released unmarked legal-size Chinook, 267 retained sublegal-size fish ( 246 marked, 21 unmarked), and 5,341 sublegal-size released Chinook (4,281 marked and 1,060 unmarked) (Table 24).

Given Method-2 encounters, we estimated the total Chinook mortality during this fishery at 8,155 fish (Table 25), the majority of which ( $94 \%$ ) were marked. These estimated mortalities were comprised of 6,582 retained legal-size fish (6,532 marked and 50 unmarked), 237 released unmarked legal-size Chinook, 267 retained sublegal-size fish (246 marked, 21 unmarked), and 1,068 sublegal-size released fish (856 marked and 212 unmarked) for both areas combined.

## Comparison of Methods 1 and 2

Combined Areas 9 and 10 season-total encounter and mortality estimates differed appreciably between Methods 1 and 2. Method-2 encounters (13,770), based on expanded dockside observations of legal-marked Chinook (i.e., using the legal-marked proportion of
test-boat encounters), were $43 \%$ less than interview-based Method-1 encounters (24,045). In contrast to total encounters, estimated mortalities diverged less between methods; there was a $17 \%$ difference between Methods 2 and 1 ( 8,150 vs. 9,870 mortalities, respectively) for this quantity.

Given the disparity in results from the two methods and the importance of encounter and mortality estimates to total fishery-impact assessment, we briefly consider the potential sources of the observed disparity in results here. Method 1 yielded estimates (retention + release) suggesting anglers released nearly half ( $46 \%$ ) of the legal-marked Chinook salmon that they caught (i.e., they were "sorting" their catch at a high level). Considering the moderate catch rates estimated for Areas 9 and 10 fisheries ( $\sim 1$ fish retained per 4 and 6 angler trip, respectively) and the two-fish bag limit, we believe that sorting of this magnitude is unlikely and thus a result of anglers over-reporting releases during dockside interviews. Conversely, it is also unlikely that anglers kept all legal-size, marked fish encountered, as anglers do occasionally release fish that are marginally larger than the legal minimum with hopes of landing a larger fish. Even in low-success winter fisheries, charter-boat anglers are known to release $\sim 10 \%$ of all legal-marked encounters (e.g., Areas 8-1/8-2; WDFW 2007a, 2007c). In combination, these considerations suggest the true number of Chinook encountered and impacted by the Areas 9 and 10 selective Chinook fisheries is between Method-1 and Method-2 estimates.

In sum, the true total number of Chinook encountered during the course of the 9 and 10 fisheries is likely between 13,770 (Method 2) and 24,045 (Method 1); the true number of fishery-related mortalities is likely between 8,155 (Method 2) and 9,870 (Method 1).

Table 22. Summary of season-wide (July 16-31 for Area 9 and 16-28 for Area 10) impact (encounters and total mortality) estimates for Marine Areas 9 and 10. The values displayed were derived by summing stratum-specific encounters and mortalities (and variances) using the "Method-1" estimation approach (See Appendix A for further detail). Method 1 uses the number of Chinook encounters obtained from dockside creel estimates for each stratum, combined with counts from charter boats and apportions total encounters to the four categories of legal marked, legal unmarked, sublegal marked, and sublegal unmarked, according to the stratum-specific proportions of those fish caught in the test fishery in each area. Values may not add exactly due to rounding error.

Table 23. Estimated encounters of Chinook in areas 9 (July 16-31, 2007) and 10 (July 16-28, 2007) Chinook selective fisheries based on "Method 2", which assumes that anglers retained all legal-size marked Chinook. Total encounters were estimated by dividing the number of legal-size marked Chinook that anglers retained by the weighted proportion of legal-size marked fish from the test boats. The number of encounters in the remaining three categories was then obtained by multiplying the total encounters by the proportions for each corresponding category. Values may not add exactly due to rounding error.

Table 24. Comparison of methods used to estimate encounters of Chinook in the Areas 9 and 10 Chinook selective fisheries during July 2007. Method 1 applies the size/mark-status proportions from test fishing data to the number of encounters estimated from creel surveys (combined with counts of encounters reported from charter boats). Method 2 assumes that anglers did not release any legal-size marked fish, and total encounters are estimated by dividing the number of legal-size marked Chinook retained by the proportion of legal-size marked fish observed by the test fishery during each stratum, and then summed across the whole season; the number of encounters in the remaining three categories was then obtained by multiplying the total encounters by the proportions for each corresponding category. See Appendix A for more details on Method-1 versus Method-2 estimation. Values may not add exactly due to rounding error.

## Observed versus Predicted Encounters and Mortalities

To place the estimated impact of the Areas 9 and 10 Chinook selective fisheries into context, we contrasted post-season estimates of total encounters and mortalities generated using Method 1 with pre-season management expectations generated using the Fishery Regulation Assessment Model (FRAM; Model 3907). Pre-season FRAM predictions suggested the areas 9 and 10 fisheries would result in a total of 20,680 total Chinook encounters ( 10,075 legal and 10,605 sublegal Chinook), 7,000 of which would be landed (all legal, 230 unmarked, 6,770 marked; Table 26); we estimated that anglers actually encountered 24,045 Chinook (14,954 legal and 9,091 sublegal) of which 6,850 were landed ( 71 unmarked, 6,779 marked). With the exception of legal-marked encounters (observed encounters exceeded modeled values by $48 \%$ ), observed encounters were similar to FRAM-modeled impacts. Further, observed unmarked-Chinook encounter estimates (i.e., legal, sublegal, and landed-only, by area and overall) were generally less than and within $5 \%$ of modeled values (Table 26).

Similar to our modeled versus observed encounters comparison, differences between pre-season modeled mortalities and actual (estimated) values were minimal overall and within marine-area and size/mark-status classes (Table 27). Pre-season predictions suggested 9,932 Chinook mortalities would occur ( 7,000 retention and 2,932 post-release mortalities) as a result of the 9 and 10 fisheries. We estimated that 9,870 Chinook ( 6,850 retention and 3,020 post-release mortalities) mortalities actually occurred due to the fishing activity that occurred in the two marine areas. Similar to total encounters, post-release mortality observations for legal-size Chinook (especially marked fish) exceeded pre-season predictions by $55 \%$. More importantly, observed unmarked-Chinook mortalities were either comparable to ( $<10 \%$ divergent) or less than FRAM predictions in all cases.

In combination, our observed-versus-predicted encounters/mortalities comparison suggests that the Areas 9 and 10 fisheries operated within the conservation constraints defined by managers during pre-season fishery planning.

Table 26. Comparison of observed Chinook encounters based on estimates from creel surveys, versus Chinook encounters predicted from the FRAM model (final model run 3907), for Areas 9 and 10 combined from July 16-31 (Area 9) and July 16-28 (Area 10), 2007.

a. We used the number of Chinook encounters obtained from dockside creel estimates and apportioned these total encounters into the four categories of legal marked, legal unmarked, sublegal marked, and sublegal unmarked, according to the proportions of those fish caught in the test fishery in Areas 9 and 10 ("Method 1"). The total encounters also include counts of Chinook encounters from charter vessels (sizes and mark status of these Chinook were known).

Table 27. Comparison of observed Chinook mortalities based on estimates from creel surveys, versus Chinook mortalities predicted from the FRAM model (final model run 3907), for Areas 9 and 10 combined from July 16-31 (Area 9) and July 16-28 (Area 10), 2007.

a. Mortalities were calculated based on the number of Chinook encounters obtained from dockside creel estimates, which we apportioned into the four categories of legal marked, legal unmarked, sublegal marked, and sublegal unmarked, according to the proportions of those fish caught in the test fishery in Areas 9 and 10 ("Method 1").

## SUMMARY

During July of 2007, anglers were allowed to fish for and retain Chinook in Marine Areas 9 and 10 , an angling opportunity which has not existed for more than a decade. Our sampling results for this pilot selective Chinook fishery suggest that it was highly successful with respect to the goal of increasing recreational fishing opportunity without compromising conservation goals for ESA-listed Puget Sound Chinook salmon.

Based on both test-fishing and VTR data collected during the course of the Areas 9 and 10 fisheries, we estimated that roughly two thirds to three quarters of all legal-size Chinook salmon encountered by anglers in the two areas were marked and could therefore be retained by anglers. Thus, mark rates were sufficiently high to provide acceptable harvest probabilities. Additionally, the measured impacts of the fishery were either less than or comparable to pre-season expectations for unmarked Chinook salmon and the estimated number of mortalities of unmarked CWT fish (i.e., DIT groups) was negligible. Thus, the pilot fishery resulted in acceptable levels of impact on wild Chinook salmon and did not compromise the integrity of the coast-wide coded wire tag program. Finally, in terms of implementation, the Areas 9 and 10 fisheries were successful in terms of monitoring and management; total landings closely approached but remained within the established harvest quotas.

## ACKNOWLEDGEMENTS

We thank the following individuals who contributed to this study. Several WDFW staff contributed to data collection and analysis. Slim Simpson, Larry Bennett, Steve Axtell and their sampling crews collected the data and summarized the information on a weekly basis throughout the season. The test boat operators in Area 9 were Jeff Harris and Toby Black, and the test boat operators in Area 9 were Jim Pykonen and Mike Petronelli. The samplers in northern Area 9 were Marcus Thompson, Ken Wall, Sara Witczak, and Renee Dufek. The samplers in southern Area 9 were Jenny Orr, Nolan Grose, Amy Willoughby, and Kevin Byron. Cara Crowley and Mary Raymond sampled on the west side of Areas 9 and 10. Samplers for the east side of Area 10 included Leisl Bauman and Lucas Peter. Boat survey crews included Scott Walker, Justin Benjamin, Slim Simpson and staff, as well as Steve Axtell and staff such as Dean Toba and Jim Repoz. Permanent sampling staff in Central Sound, Jeff Mckee and Kathy Young-Berg, assisted Slim Simpson in the summarization and error checking of data. The sampling crews also played a key role in education efforts for the first season of the selective Chinook fishery in Areas 9 and 10. Steve Thiesfeld provided key input regarding many aspects of data collection and analysis. Brian McTeague created the Marine Areas 9 and 10 maps. Lee Dyer and her staff provided substantial help with personnel logistics and support services for the project. Karen Kloempken managed the WDFW sampling databases and provided finalized post-season data. WDFW Biometrician Kristen Ryding provided helpful input on the data analyses. Fish and Wildlife Biologists Peter McHugh and Mark Baltzell, along with some input from Laurie Peterson, completed the bulk of the data analyses and report writing.

Appendix A. Estimating strata-specific and overall selective-fishery impacts in Areas 9 and 10
List A1. Variable definitions and equations associated with Figure A1.
Below are definitions and equations for all quantities used in estimating total mark-selective fishery impacts under "Method 1 " (defined in the main report on p .16 ). The sequence in the list builds from stratum estimators (and variances) of encounters-by-class (i.e., size/mark-status groups) to season-wide fishery-impact estimates. Where appropriate, the inclusion/treatment of charter-based encounters [kept plus released Chinook; assumed the result of a complete census (i.e., with zero variance)] in estimating particular quantities of interest is also provided (see p. 13 in the main report body for background on this topic); those instances are denoted by the symbol $\dagger$. Further, estimation differences leading to "Method-2" estimates of fishery impacts are also identified where appropriate and are denoted by $\ddagger$. Regarding notation: i) symbols follow those in Figure A1; ii) estimated quantities appear in italics; and iii) constants (with an assumed variance of zero) are depicted in bold-faced, italicized font.

## A. Total and class-specific encounters estimation:

The first step towards quantifying mark-selective fishery impacts by size/mark-status class is the apportioning of Murthy-based estimates of total Chinook encounters (the sum of retained and released fish; Stratum Encounters) in a given stratum $i$ to the appropriate group using encountercomposition data collected in the WDFW test fishery (Test-fishery Encounter Composition).

## Stratum Encounters

$E_{i}=\quad$ Estimated total Chinook encounters for stratum $i$, inclusive of retained and released individuals from all mark-status groups ( $N_{\mathrm{MK} i}=$ marked-retained, $N_{\mathrm{UK} i}=$ unmarkedretained, $N_{\mathrm{MR} i}=$ marked-released, and $N_{\mathrm{UR} i}=$ unmarked-released), released Chinook of unknown mark status ( $N_{\mathrm{unkR}}$ ), and apportioned unidentified salmon [ $N_{\mathrm{AUS} i}$, i.e., unidentified (to species) released salmonids that may have been Chinook; apportioned by identified-released proportions] derived using the Murthy estimator. $E_{i}$ and its variance are estimated as:

$$
\begin{gather*}
E_{i}=N_{\mathrm{MK} i}+N_{\mathrm{UK} i}+N_{\mathrm{MK} i}+N_{\mathrm{UK} i}+N_{\mathrm{UnkK} i}+N_{\mathrm{AUS} i}  \tag{1}\\
\operatorname{var}\left(E_{i}\right)=\operatorname{var}\left(N_{\mathrm{MK} i}\right)+\operatorname{var}\left(N_{\mathrm{UK} i}\right)+\operatorname{var}\left(N_{\mathrm{MR} i}\right)+\operatorname{var}\left(N_{\mathrm{UR} i}\right)+  \tag{2}\\
\operatorname{var}\left(N_{\mathrm{UnkR} i}\right)+\operatorname{var}\left(N_{\mathrm{AUS} i}\right)^{1}
\end{gather*}
$$

$\dagger$ If $E_{i}$ is being estimated for the sake of characterizing encounters in stratum $i$ (regardless of size-mark status) alone, all charter encounters $\boldsymbol{E}_{\text {charti }}$ (retained + released) should be incorporated into 1 above; otherwise, $\boldsymbol{E}_{\text {charti }}$ is incorporated into class specific estimates (i.e., if class-specific encounters or mortalities are of interest).
$\ddagger$ For Method-2, the total stratum encounter estimate, $E_{i}$, is obtained by: 1) combining the marked-legal retention estimate ( $K_{\mathrm{LM}}$ ) and the test-fishery-based estimate of the proportion of at-large Chinook that are marked and of legal size ( $p_{\mathrm{LM}}$; defined in 3 and 9 below) and 2 ) assuming that anglers retain all legal-size,

[^0]marked Chinook [i.e., $E_{i}=K_{\mathrm{LM} i} / p_{\mathrm{LM} i}$, with $\operatorname{var}\left(E_{i}\right)=\left(K_{\mathrm{LMi}}{ }^{2} / p_{\mathrm{LM} i}{ }^{2}\right) *\left(\operatorname{var}\left(K_{\mathrm{LM} i}\right) / p_{\mathrm{LM} i}{ }^{2}+\operatorname{var}\left(p_{\mathrm{LM} i}\right) /\right.$ $\left.K_{\mathrm{LM}}{ }^{2}\right)$ ]. This estimate is used in all subsequent Method-2 computations in a manner identical to Method-1 $E_{i} \mathrm{~S}$ unless specified otherwise.

## Test-fishery Encounter Composition

$p_{\mathrm{LM} i}=$ the test-fishery estimate of Chinook catch proportion comprised of legal (L), marked (M) individuals during stratum $i$,
$p_{\mathrm{LU} i}=$ the test-fishery estimate of Chinook catch proportion comprised of legal (L), unmarked (U) individuals during stratum $i$
$p_{\mathrm{SM} i}=$ the test-fishery estimate of Chinook catch proportion comprised of sublegal (S), marked (M) individuals during stratum $i$
$p_{\mathrm{SU} i}=$ the test-fishery estimate of Chinook catch proportion comprised of sublegal (S), unmarked (U) individuals during stratum $i$

For each $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), test-fishery $p_{X Y i} \mathrm{~S}$ and their variances are estimated as:

$$
\begin{align*}
& p_{X Y i}=N_{X Y i} / \Sigma N_{X Y i}, \text { and }  \tag{3}\\
& \operatorname{var}\left(p_{X Y i}\right)=\left[p_{X Y i}^{*}\left(1-p_{X Y i}\right)\right] /\left(n_{i}-1\right), \tag{4}
\end{align*}
$$

where $n_{i}=$ the total number of fish encountered by test boats during stratum $i$.
Note: to increase the sample size used to quantify test-fishery catch composition, $p_{X Y i}$ estimates were generated for statistical weeks rather than for individual 1-4 day strata; these estimates, however, were used in the same manner as described above.

## Encounters by Size/Mark-status Class

$E_{\mathrm{LM} i}=$ estimated legal (L), marked $(\mathrm{M})$ encounters during stratum $i$
$E_{\mathrm{LU} i}=$ estimated legal (L), unmarked ( U ) encounters during stratum $i$
$E_{\mathrm{SM} i}=$ estimated sublegal (S), marked (M) encounters during stratum $i$
$E_{\mathrm{SU} i}=$ estimated sublegal (S), marked (U) encounters during stratum $i$
For each $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), apportioned encounters $E_{X Y i}$ and a conservative estimate of its variance (assuming $\mathrm{p}_{\mathrm{XYi}}$ and $\mathrm{E}_{\mathrm{XYi}}$ are independent estimates) are obtained from:

$$
\begin{align*}
& E_{X Y i}=E_{i}^{*} p_{X Y i}  \tag{5}\\
& \operatorname{var}\left(E_{X Y i}\right)=\operatorname{var}\left(E_{i}\right)^{*} p_{X Y i}^{2}+E_{i}^{2 *} \operatorname{var}\left(p_{X Y i}\right) \tag{6}
\end{align*}
$$

$\dagger$ If $E_{X Y i}$ is being estimated for the purpose of characterizing class-specific encounters during stratum $i$ alone, charter encounters broken down by class [i.e., $\boldsymbol{E}_{\text {chartXYi }}$ (retained + released)] should be incorporated into 5 above; otherwise, $\boldsymbol{E}_{\text {chartXYi }}$ s are incorporated into estimators below (i.e., if class-specific mortalities are of interest).
$\ddagger \operatorname{var}\left(E_{X Y i}\right)$ (i.e., equation 6) includes an additional covariance component [i.e., $\operatorname{var}\left(E_{i}\right) * \operatorname{var}\left(p_{X Y i}\right)$ ] for Method-2 estimates of apportioned encounters given that $E_{i}$ is derived from test-fishery data.

## B. Estimating Retained and Released Numbers by Size/Mark-status Class:

Before mortality can be estimated for each class, the number of fish retained and released must be estimated. Class-specific retention estimates are obtained by apportioning Murthy estimates of marked and unmarked Chinook retained in each stratum $i$ to size classes (Apportioned Estimates of Retention to Size Classes); this is achieved using proportions estimated during dockside creel surveys (Dockside Observations for Apportioning Retained Catch to Class). Releases are then estimated as the difference between class-specific total encounters and retention (Estimating Release Numbers by Class).

Dockside Observations for Apportioning Retained Catch to Class
$d_{\mathrm{LMK}}=$ the estimated proportion of retained (kept, K), marked (M) Chinook salmon that were legal ( L ); based on season-wide dockside observations of marked Chinook (as is $d_{\text {SMK }}$ )
$d_{\text {SMK }}=$ the estimated proportion of retained (kept, K), marked (M) Chinook salmon that were sublegal (S)

The proportion of retained, marked fish in size class $X(X=\mathrm{L}$ or S$)$ and its variance are estimated as:

$$
\begin{align*}
& d_{X \mathrm{MK}}=n_{X \mathrm{MK}} / \Sigma n_{X \mathrm{MK}}  \tag{7}\\
& \operatorname{var}\left(d_{X \mathrm{MK}}\right)=\left[d_{X \mathrm{MK}}{ }^{*}\left(1-d_{X \mathrm{MK}}\right)\right] /\left(\Sigma n_{X \mathrm{MK}}-1\right),
\end{align*}
$$

where $\Sigma n_{X \mathrm{MK}}$ and $n_{X \mathrm{MK}}$ are season-wide total dockside counts of marked fish and the subset of marked fish in size-class $X$, respectively.
$d_{\text {LUK }}=$ the estimated proportion of retained (kept, K), unmarked (U) Chinook salmon that are legal (L) ; estimated from season-wide dockside observations of unmarked Chinook (as is $p_{\text {SUK }}$ )
$d_{\text {SUK }}=$ the estimated proportion of retained (kept, K), unmarked (U) Chinook salmon that are sublegal (S)

The proportions of retained, unmarked fish belonging to legal and sublegal size classes are estimated as above (7 and 8) but using season-wide dockside observations on unmarked (U), not marked Chinook salmon.

Apportioned Estimates of Retention to Size Classes
$K_{\mathrm{LM} i}=$ estimated number of legal (L), marked (M) Chinook kept in stratum $i$
$K_{\mathrm{LU} i}=$ estimated number of legal (L), unmarked (U) Chinook kept in stratum $i$
The number of kept, marked encounters, marked fish in size class $X$ (legal or sublegal) and its variance is estimated as:
(9) $\quad K_{X \mathrm{M} i}=d_{X \mathrm{MK}} * N_{\mathrm{MK} i}$

$$
\begin{equation*}
\operatorname{var}\left(K_{X M i}\right)=\operatorname{var}\left(N_{\mathrm{MK} i}\right)^{*} d_{\mathrm{XMK}}{ }^{2}+N_{\mathrm{KM} i}{ }^{2} * \operatorname{var}\left(d_{X \mathrm{MK}}\right)+\operatorname{var}\left(N_{\mathrm{MK}}\right)^{*} \operatorname{var}\left(d_{\mathrm{XMK}}\right) \tag{10}
\end{equation*}
$$

where $d_{X \mathrm{MK}}$ and its variance are from 7 and 8 above and $N_{\mathrm{MK} i}$ is the Murthy estimate of retained marked fish for stratum $i$ defined for 1 above.
$K_{\text {SM } i}=$ estimated number of sublegal (S), marked (M) Chinook kept in stratum $i$
$K_{\mathrm{SU} i}=$ estimated number of sublegal (S), unmarked (U) Chinook kept in stratum $i$
The number of retained, unmarked fish belonging to legal and sublegal size classes is estimated as above ( 9 and 10) using unmarked fish proportions and stratum-specific Murthy-based retention estimates (and variances).

## Estimating Release Numbers by Class

$R_{\mathrm{LM} i}=$ estimated number of legal (L), marked (M) Chinook released in stratum $i$
$R_{\mathrm{LU} i}=$ estimated number of legal (L), unmarked (U) Chinook released in stratum $i$
$R_{\mathrm{SM} i}=$ estimated number of sublegal (S), marked (M) Chinook released in stratum $i$
$R_{\mathrm{SU} i}=$ estimated number of sublegal (S), unmarked (U) Chinook released in stratum $i$
For each size/mark-status class $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), the number fish encountered and released is estimated as the difference of total size/markstatus class encounters ( $E_{X Y i}$ ) and retention ( $K_{X Y i}$ ) during stratum $i$. The estimator and its variance are:

$$
\begin{align*}
& R_{X Y i}=E_{X Y i}-K_{X Y i}  \tag{11}\\
& \operatorname{var}\left(R_{X Y i}\right)=\operatorname{var}\left(E_{X Y i}\right)+\operatorname{var}\left(K_{X Y i}\right) \tag{12}
\end{align*}
$$

$\dagger$ Charter-reported $\boldsymbol{R}_{X Y i} \mathrm{~s}$ are incorporated into equation 11 for complete $R_{X Y i}$ estimation.
$\ddagger \ddagger$ For Method-2, $R_{\mathrm{LM} i}$ is assumed to be zero with zero variance (i.e., anglers retain all legal-size, marked fish); all other $R_{X Y i} \mathrm{~s}$ are estimated using equations 11 and 12 , but with Method-2-specific $E_{X Y i} \mathrm{~s}$.

## C. Estimating Total (and Class-specific) Stratum-specific and Season-wide Mortality:

The final step towards quantifying mark-selective fishery impacts is the application of assumed mortality rates (Assumed Mortality Rates for Retained and Released Chinook) to class-specific retention and release estimates.

Assumed Mortality Rates for Retained and Released Chinook<br>$\boldsymbol{m}_{\mathbf{K}}=$ retention mortality rate, $100 \%$ for all retained Chinook<br>$\boldsymbol{s f m _ { L }}=$ release mortality rate for legal (L) Chinook, assumed to be a constant $15 \%$<br>$\boldsymbol{s f m _ { \mathrm { S } }}=$ release mortality rate for sublegal (S) Chinook, assumed to be a constant $20 \%$

## Retention-mortality Estimates

$M_{\text {LMKi }}=$ estimated number of mortalities due to direct harvest of legal $(L)$, marked ( $M$ ) Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\mathrm{LM} i}$ given that $m_{\mathrm{K}}=1.00$ (i.e., $M_{\mathrm{LMK} i}=K_{\mathrm{LM} i}{ }^{*} \boldsymbol{m}_{\mathbf{K}}$ ).
$M_{\mathrm{LUK} i}=$ estimated number of mortalities due to direct harvest of legal $(L)$, unmarked ( $U$ )
Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\text {LUi }}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\mathrm{LUK} i}=K_{\mathrm{LU} i}{ }^{*} \boldsymbol{m}_{\mathrm{K}}$ ).
$M_{\text {SMK } i}=$ estimated number of mortalities due to direct harvest of sublegal ( $S$ ), marked ( $M$ )
Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\text {SMi }}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\mathrm{SMK} i}=K_{\mathrm{SM} i}{ }^{*} \boldsymbol{m}_{\mathrm{K}}$ ).
$M_{\text {SUK } i}=$ estimated number of mortalities due to direct harvest of sublegal $(S)$, unmarked ( $U$ ) Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\text {SUi }}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\mathrm{SUK} i}=K_{\mathrm{SU} i}{ }^{*} \boldsymbol{m}_{\mathrm{K}}$ ).
$\dagger$ Charter-reported $\boldsymbol{K}_{X Y i}$ are added to the appropriate $\mathrm{M}_{X Y i}$ for complete retention-mortality estimation.

## Release-mortality Estimates

$M_{\mathrm{LMR} i}=$ estimated number of post-release, fishery-related mortalities of encountered legal $(L)$, marked ( $M$ ) Chinook in stratum $i$
$M_{\text {LUR } i}=$ estimated number of post-release, fishery-related mortalities of encountered legal $(L)$, unmarked ( $U$ ) Chinook in stratum $i$
$M_{\text {SMR } i}=$ estimated number of post-release, fishery-related mortalities of encountered sublegal $(S)$, marked ( $M$ ) Chinook in stratum $i$
$M_{\text {SUR } i}=$ estimated number of post-release, fishery-related mortalities of encountered sublegal ( $S$ ), unmarked ( $U$ ) Chinook in stratum $i$

An estimate of release mortality for size/mark-status class $X Y(X=\mathrm{L}$ or $\mathrm{S}, Y=\mathrm{M}$ or U$)$ in stratum $i$ and its variance is obtained from:
(13) $\quad M_{X Y R i}=R_{X Y i} * s f m_{Y}$
(14) $\operatorname{var}\left(M_{X Y R i}\right)=\operatorname{var}\left(R_{X Y i}\right) * \operatorname{sfm}_{Y}{ }^{2}$

## Season-wide Total and Class-specific Mortality Estimation

$M_{\text {total }}=$ season-wide Chinook mortality due to the selective fishery; this parameter and its variance $\left[\operatorname{var}\left(M_{\text {total }}\right)\right]$ are computed as the sum of all strata-specific retention $\left(M_{X Y K i}\right)$ and release mortality $\left(M_{X Y \mathrm{R}}\right)$ estimates and variances, respectively, for the $X Y(X=\mathrm{L}$ or $\mathrm{S}, Y$ $=\mathrm{M}$ or U ) size/mark-status groups; similarly, mortality estimates and variances for subgroups of interest (e.g., unmarked, sublegal Chinook, $M_{\text {SU-total }}$ ) are estimated by summing estimates/variances across strata for the season for that class.

The standard error (SE), coefficient of variation (CV), and 95\% confidence interval about $M_{\text {total }}$ (and all other parameters $\theta$ defined herein) are obtained from:
(16) $\mathrm{CV}(\theta)=[\mathrm{SE}(\theta) / \theta] * 100$
(17) $95 \% \mathrm{CI}=\theta \pm 1.96 * \mathrm{SE}(\theta)$

Figure A1. Graphical representation of the estimation approach used to quantify stratumspecific encounters and mortalities by size/mark-status category for the Areas 9 and 10 selective Chinook fishery during July 2007. Boxes depict abundance estimates (encounters, mortalities) whereas the mathematical operations depicted on intermediate connector lines are estimator formulae for subsequent boxes (moving from left to right). Gray ovals represent points in the total encounter and mortality estimation sequence where Methods 1 and 2 diverge. Variable and parameter names, complete formulae, and variances (where appropriate) are defined in List A1. Bold-faced, italicized symbols are constants, all others are estimated quantities. Total stratum mortality is the sum of $M_{\mathrm{K} i}$ and $M_{\mathrm{R} i}$; the season-wide estimate is the sum of all strata estimates.

Appendix F. Sites sampled for the creel survey estimate in Areas 9 and 10 by sample date. Sites-size measures calculated from boat-survey data during the July 2007 selective Chinook fisheries are provided for all sampled sites.
