## EXECUTIVE SUMMARY

## Introduction

Five years of the Area 5 and 6 "pilot" mark-selective Chinook salmon (Oncorhynchus tshawytscha) fishery, including the monitoring/sampling programs needed for evaluation of the fishery, have been completed. This multi-year report has been produced to review achievement of the purpose for implementing pilot selective Chinook fisheries in Areas 5 and 6 during the 2003 through 2007 seasons. The pilot fishery purpose is:
"The purpose of the 'pilot' fishery is to collect information necessary to enable evaluation and planning of potential future mark-selective fisheries. The 'pilot' fishery provides a basis for determining if the data needed to estimate critical parameters can be collected and if the sample sizes needed to produce these estimates with agreed levels of precision can be realistically obtained."

These monitoring and sampling programs were designed to collect and provide data to estimate the following parameters:

- the mark rate in the fishery;
- the incidence of partial adipose clips;
- the number of fish retained or landed;
- the number of unmarked fish released;
- the number of unmarked fish retained;
- the number of marked fish released;
- the number of the Chinook encounters that are of sub-legal size;
- the stock composition of the mortalities;
- estimates of marked and unmarked mortalities of double-index tagged (DIT) and other CWT stocks.

With the exception of partial adipose-clip incidence (bullet 2) and DNA-based stock composition (bullet 8), we evaluate each of the above parameters in this multi-year review document. Additionally, we present analyses of several other parameters of significance to the evaluation and future management of selective Chinook fisheries.

This report was completed by WDFW, while incorporating extensive review and input from the Tribes. We review and analyze results of the monitoring/sampling program to evaluate if the intended objectives have been achieved. These objectives include: 1) collect information necessary to enable evaluation and planning of future potential Chinook mark-selective fisheries; and 2) determine if the data needed to estimate critical parameters can be collected and if the sample sizes needed to produce these estimates with agreed levels of precision can be realistically obtained.

During the summers of 2003 through 2007, a selective Chinook recreational fishery was implemented in waters of the Strait of Juan de Fuca including Marine Area 5 and the western portion of Marine Area 6 (hereafter: Areas 5 and 6). Each year the fishery was scheduled to start
in early July and run continuously until either the quota of harvested Chinook was attained or a set number of days was reached, whichever came first. Anglers were allowed to retain two marked (adipose fin clipped) Chinook salmon $\geq 22$ " ( 56 cm ) as part of their daily limit, and were required to immediately release, unharmed, any unmarked Chinook caught. During the Chinook Selective Fishery anglers were also allowed to retain pink (O. gorbuscha), sockeye (O. nerka), and marked hatchery coho ( $O$. kisutch) salmon.

## Methods

During the summers of 2003 through 2007, we implemented separate sampling programs in Areas 5 and 6 in order to collect the data necessary to estimate daily estimates of total catch (landed and released) and total effort which could be expanded to weekly, monthly, and ultimately season-total values. Our sampling program incorporated comprehensive and complementary data collection strategies, including: 1) dockside-based angler interviews and catch sampling ("creel sampling"); 2) on-the-water total (instantaneous) effort surveys; 3) test fishing; and 4) voluntary reports of completed trips provided by charter boats and private anglers.

## Results

## Creel Sampling Results

Over the 5 years of study, the combined Areas 5 and 6 fishery lasted from 30 to 49 days. The harvest quota was obtained each year, except for 2005. Total fishing effort averaged 22,00034,000 angler trips per year (angler trips and anglers are used interchangeably throughout the document) and varied as a function of season length and catch fishing success. Chinook harvest ranged from 2,078 to 4,096 and was within $5 \%$ of the quota during years when it was met. On average, $81 \%$ of the Chinook harvest occurred in Area 5. Estimated total released Chinook encounters ranged from 6,408 to 14,841, the majority of which occurred in Area 5 each year. The number of Chinook released for every Chinook harvested declined by ~50\% (from 4.2 to 2.1) across the five years of the fishery. Chinook harvest per angler ( $\mathrm{C} / \mathrm{F}$ ) ranged from 0.06 to 0.19 and averaged 0.13 for all 5 years. For all legally harvestable salmon species combined (i.e., Chinook, coho, and pink), C/F ranged from 0.18 to 0.81 ; angling effort appeared to be correlated with total (all salmon species) C/F but not C/F for any particular salmon species.

Based on dockside sampling of landed catch and angler-reported release estimates for known mark-status Chinook, overall Chinook mark rates (legal + sublegal) were consistently higher in Area 6 than Area 5 and increased consistently from 2003 (0.24) to 2007 (0.45). The percentage of harvested Chinook that were unmarked (sublegal-size and legal-size) ranged from $0.14 \%$ to 3.03\%.

During the five seasons, dockside samplers measured the lengths of 3,517 Chinook. Harvested Chinook in Area 6 were signficantly larger than those taken in Area 5. Over 92\% of the Chinook harvested were legal-size and marked; 4-7\% of Chinook harvest was sublegal-size and 0-3\% were unmarked.

## Test Fishery Results

Test boat samplers averaged 37 days on fishing annually in Area 5 and 40 days in Area 6, yielding over 1,000 Chinook encounters. Samplers fished predominantly using downriggers ( $>69 \%$ ), as this was the predominant private-fleet fishing mode, and caught over $90 \%$ of their Chinook using this method. Season-total Chinook encounters averaged 266 for the pooled areas and total mortalities attributable to test fishing ranged from 25 to 82 annually. The majority of Area 5 test-fishery encounters were legal-size, except during 2003; Area 6 encounters were almost exclusively legal-size. Test-fishing data indicated that marked proportions were higher in Area 5 than in Area 6 in all years; Area- 5 mark rates increased over the last 5 years but showed no apparent trend in Area 6. Although Chinook mark-status/size proportions differed markedly between areas, both showed progressive increases in the legal-size and marked proportion over the course of the study. Chinook encountered by test boats were significantly larger in Area 6 than in Area 5.

## Voluntary Trip Report Results

The number of Chinook reported on Voluntary Trip Reports (VTRs) varied dramatically over the 5 years of the fishery, ranging from 37 (2006) to 213 (2003). VTR-based estimates of legal-size Chinook mark rates ranged from 20 to $100 \%$ and, similar to test boats, VTRs suggested that this value was higher in Area 6 than Area 5. Further, VTRs indicated that very few ( $<20 \%$ ) sublegal-size fish were present in Area 6. Marked, legal-size Chinook release rates estimated from VTRs ranged from 0 to $14 \%$ and averaged $5 \%$ for all years and both areas.

## Encounters and Total Mortalities

Annual encounter estimates for both areas combined ranged from 8,558 to 18,662 using Method 1 and 6,362 to 13,476 using Method 2. Method-1 estimates of total encounters for the combined areas were consistently higher Method-2 values for all years. Season-total mortality estimates (harvest and release) for the pooled areas ranged from 3,465 to 6,356 using Method 1 and 3,078 to 5,449 using Method 2. Estimated total (both methods) unmarked encounters and unmarked mortalities generally declined across the 5-year study period. The ratio of unmarked mortalities (Method 1 or 2) to harvested marked legal-size Chinook dropped steadily from 2003 through 2007, e.g. from 0.73 to 0.32 .

## CWT analysis

Over 540 coded wire tags (CWTs) were collected during the Areas 5 and 6 selective Chinook fisheries. Puget Sound and Columbia River stocks contributed the highest proportion of CWTs. Only five of the recovered CWTs were from stocks originating from rivers on the Washington side of the Strait of Juan de Fuca. The number of Double Index CWT recoveries ranged from 33 to 41, which translates into an unmarked DIT mortality estimate that ranged from 11 to 16 .

## Enforcement

The number of contacts made by enforcement officers ranged from 439 to 846 annually. Of those contacts, the proportion with sublegal-size Chinook was less than 0.01 for all areas and years. The proportion of contacts with unmarked Chinook ranged from 0.00 to 0.03 .

## SECTION I SUMMARY AND DISCUSSION

## Catch and Effort

The Areas 5 and 6 selective Chinook fisheries were driven by catch rate. During years that fishing was good, angler trips were up; during years that fishing was poor, angler trips were down. Surprisingly, the Chinook catch rate does not appear to be the main factor, but rather it appears that the overall salmon catch rate is the main factor responsible for how many angler trips are expended each season.

Selective fisheries effort was higher than effort during previous non-selective periods. For 2006 and 2007, the selective fisheries effort in Area 5 was lower than the effort in 2001, but was higher than the effort in 2002. Results of this study suggest that given the low catch rate of coho in 2003 through 2007, the addition of the selective Chinook fishery increased effort (angler trips) in each year of the fishery relative to what effort would have been without the selective Chinook fishery. Effort in Area 5 increased over what was seen during the 1994-2000 period, when no Chinook retention was allowed and coho fishing was closed at times. However, effort was considerably less than that seen for the 1984-1993 period. Effort in Area 6 does not show an increase compared to the 1994 through 2000 period. Opening a selective Chinook season did not increase effort to levels that were higher than or even near historical values.

Another issue that concerned managers and anglers prior to implementation of the 5/6 fishery was whether or not Chinook salmon mark rates would be adequate for successful fishing under mark-selective regulations; legal-size Chinook mark rates for $5 / 6$ have been good and increased in recent years. Anglers have been able to retain $50 \%$ of all legal-size Chinook encountered.

Average daily havest has ranged from approximately 50 to 115 fish per day. For future fisheries planning, assuming 100 Chinook harvested per day would be a good conservative estimate. Assuming 100 fish harvested per day for a thirty-day fishery would equate to 3,000 Chinook. For comparison, if the actual number harvested was 116 fish per day (the highest value observed), the harvest would be 3,480 or $16 \%$ over the predicted value.

## CWT Analyses

Based on CWT recoveries, the Area 5 and 6 selective Chinook fishery appears to impact mainly Puget Sound and Columbia River stocks. For Strait of Juan de Fuca hatchery stocks, less than 1 percent of all CWT recoveries occur in Washington recreational fisheries; in contrast, nearly 29 percent of the recoveries occurr in Canada and Alaska. Based on our estimates of unmarked DIT

Chinook mortalities, the overall bias introduced to the CWT program due to this fishery is extremely low.

## Enforcement Compliance Compared to Creel Compliance

For most areas and years, creel-survey results suggest a higher proportion of either unmarked or sublegal-size Chinook retention than enforcement reports indicate. However, both creel survey and enforcement data suggest compliance was high ( $90 \%$ during all years and in both areas).

## SECTION II: Assessment of the selective fishery sampling program and analysis methods

Sampling intensity-related questions:
In general, we successfully met sampling objectives. During the five study years, the precision of both harvest and effort estimates approached or exceeded the 0.15 precision objective. Sample-size objectives for dockside encounters ( 100 / month) were met in most cases, the exception being Area 6 (2005-2007 during August). Weekly sample rates ( $n$ fish examined / estimated harvest) exceeded the CWT sample-rate goals, ranging from 0.154 to 0.544 in Area 5 and 0.162 to 0.777 in Area 6. At the season-total level, sample rates ranged from 0.227 to 0.276 in Area 5 and from 0.326 to 0.558 in Area 6. Finally, test-fishery sampling objectives were generally well met in Area 5, but not Area 6.

## Comparing Private Fleet, Test Fishing, and VTR data

A key assumption of our monitoring program is that the test-fishery and private-fleet encounter composition (i.e., frequency by size/mark-status class) is the same (Assumption 6). To evaluate this assumption, we compared the mark rates, length, and mark-status/size composition of fish caught by the private fleet (from creel surveys and VTRs) and and test fishers.

Length-frequency distributions (for legal-marked Chinook) were similar when compared between test fishery and creel samples within areas and years, but remarkably different when compared between areas and within sampling methods and years. Thus, while both the test fishery and fleet "sampled" legal-marked Chinook in a manner that could discriminate gross differences between areas, they produced statistically indistinguishable length results within areas. Mark rate and mark-status/size comparison results were more variable than those from length comparisons. First, overall mark rates estimated from creel surveys occasionally differed with those estimated from both test-fishery and VTR datasets during most years in Area 5, but only one year in Area 6. Second, test-fishery and VTR mark-rate estimates differed infrequently. Third, for the majority of area-year combinations, legal-size Chinook mark rate estimates produced from test-fishery and VTR data were statistically indistinguishable. Finally, markstatus/size comparisons suggested similarlity between groups but produced inconsistent results.

## Estimation of Total Encounters, Method 1 versus Method 2

To determine whether Method 1 or Method 2 provides a more accurate estimate of total Chinook encounters in selective fisheries, we evaluated: $i$ ) Method-1 and -2 total-encounters estimators and their associated assumptions, $i i$ ) the sensitivity of estimators to assumption violations, and iii) the validity of assumptions based on indirect evaluations using empirical data. Method 1 (M1, sum of creel-based estimates for all Chinook encounters categories) and Method 2 (M2, creel-based estimate of legal-marked Chinook landed catch expanded by test-fishery legalmarked proportion) differ computationally and in terms of the assumptions they require for accurate encounters estimation. M1 accuracy relies on the ability and/or willingness of anglers to accurately recall and/or report caught-and-released Chinook encounters (Assumption 3). The accuracy of M2 estimates depends on whether or not anglers report all legal-marked Chinook encountered (Assumption 5) and the extent to which the size/mark-status composition of testfishery encounters mirrors that seen by private anglers (Assumption 6 ).

Our M1 vs. M2 sensitivity analysis revealed that: $i$ ) when Assumptions 3 and 5 are not met, M1 and M2 estimates are affected similarly, ii) estimates are most sensitive to Assumption 6 departures, and $i i i$ ) due to compensating effects, M2 has the potential to yield accurate encounters estimates when both Assumption 5 and 6 are imperfectly met. Next, we considered available empirical evidence to gauge the plausibility of Assumptions 3, 5, and 6. For Assumption 3 ("Anglers accurately report released Chinook encounters"), we reviewed pertinent literature, considered patterns in M1 relative to M2 estimates, and inspected raw interview data (i.e., release-frequency distributions). Based on this, we concluded that Assumption 3 is unlikely to be perfectly met-particularly during high-encounters periods-and that in general anglers probably over-report released Chinook encounters. Though few data exist for evaluating Assumption 5, available information suggests that it is violated to a minor degree. Based on voluntary trip reports, we estimate that anglers may release approximately $5 \%$ (range: $0-14 \%$ ) of the legal-marked Chinook that they encounter. Finally, we considered the likelihood of meeting Assumption 6 in our test fishery vs. creel/VTR comparison described above. This evaluation suggested that Assumption 6 is reasonably met in the Areas 5 and 6 sampling program.

## FRAM Performance in Selective Fishery Planning

FRAM predictions were relatively accurate for the Area 5 and 6 selective Chinook fishery. Whereas estimated marked legal- and sublegal-size Chinook catch often exceeded FRAM predictions, unmarked legal-size Chinook catch never exceeded predicted values. Unmarked sublegal-size fish exceeded the FRAM predictions (zero harvest) in 3 of 5 years. Total unmarked landings were 1 to $26 \%$ of FRAM predictions.

For encounters, Method 1 estimates exceeded model predictions in 4out of 5 years for marked legal-size and 1 out of 5 years for unmarked sublegal-size fish. Despite the fact that Method 1 estimates are likely biased high (see M1 vs. M2 section), estimated total unmarked Chinook encounters never exceeded FRAM predictions. Method 2 estimates of total marked legal-size encounters exceeded FRAM predictions less frequently. Total unmarked encounters estimates
(Method 2) never exceeded model predictions, though unmarked sublegal-size encountes did so in 1 year. For mortalities (harvest + release mortality), Method 1 estimates exceeded FRAM in most cases for marked legal-size and total marked fish and in one year for marked and unmarked sublegal-size fish. Despite the fact that Method 1 estimates are likely biased high, estimated total unmarked Chinook mortality never exceeded FRAM predictions. Across the four mark-status/size categories, comparisons of Method 2 mortality estimates with FRAM predictions yielded similar results as the encounters comparsions.

For selective fishery parameters used in model runs, unmarked retention error ranged $<1 \%$ to $2 \%$, well below the FRAM value (8\%). Marked release error ranged 24-37\% (M1 estimates), much greater than the FRAM value ( $6 \%$ ). Whereas unmarked and marked sublegal-size retention error are modeled as zero in FRAM, empirical estimates for these respective parameters were $0-8 \%$ and $6-19 \%$.

## SECTION II SUMMARY AND DISCUSSION

## Sampling Intensity

Our monitoring and sampling programs were designed to collect the data needed to reliably estimate several selective fishery parameters. With few exceptions, our monitoring program was effective at sampling the 5 and 6 selective Chnook fisheries. Harvest estimates met the $15 \%$ precision objective in all years that the quota was achieved, effort estimates always met the objective; and the CWT sample rate goal was always met. Based on these results, we believe that our dockside program for summer selective Chinook fisheries with quotas should remain unchanged. Although sampling success was high for the Area 5 test fishery, Area 6 test fishers met sampling objectives less than $50 \%$ of the time. However, the objective of 100 encounters is probably unrealistic for Area 6 given that total fleet encounters ranged 683-1,614 during years when the goal was not met. An alternative test fishing objective for short duration, low catch rate fisheries should be investigated.

## Comparing Private Fleet, Test Fishing, and VTR data

Based on our results, we conclude that test boat catches are representative of angler catches for the following reasons:

- The mean lengths and length-frequency distributions of legal-size marked Chinook caught by test fishers were similar to those for Chinook caught by private fleet anglers.
- Length samples acquired via test fishing and from the private fleet (creel) both displayed clear between-area (within year) differences.
- Test fishery and VTR estimates of overall mark rates were similar.
- Legal-size Chinook mark rate estimates from VTRs and the test fishery were similar; where differences occurred, they were not in a single and consistent direction (i.e., +/-)
- Mark-status/size composition estimates from VTRs differed from test-fishery estimates in only $3 / 10$ year/area comparisons.

## CONCLUSIONS

Prior to implementation of the 2003 selective Chinook fishery, managers identified several questions about the magnitude and impacts of such fisheries that needed to be addressed through monitoring and evaluation.

## Fishery Monitoring and Results

The use of the Murthy type estimator and test fishing worked well to describe the fishery. Opening of this selective Chinook fishery did not lead to effort levels that are substantially higher than historical levels and in fact, effort was well below historical levels. The mark rate during this fishery ranged from about $40-60 \%$, and for legal-size fish from about $35-65 \%$, which increased over time. The proportion of sublegal-size fish in Area 5 dropped from 0.54 in 2003 to 0.33 in 2007, and never exceeded 0.06 of the catch in Area 6. The number of fish released per landed dropped throughout the duration of fisheries from 4.2 to 2.0. Total fishing related Chinook mortalities ranged from 2,839 to 6,193. Puget Sound and Columbia River origin stocks comprise the bulk of the fishery. Very few Strait of Juan de Fuca origin stocks are caught in this fishery. Very few DIT fish are caught in this fishery and the effect on the DIT mark rates appears undetectable. Angler compliance exceeded $90 \%$ at all times

## Use of FRAM to Predict Selective Fishery Impacts

FRAM encounter predictions were generally higher than analogous creel estimates. They were on average $16 \%$ higher than Method 1 and $64 \%$ higher than Method 2 estimates; however, FRAM tended to underestimate marked, and overestimate unmarked, encounters and catch. Mean unmarked retention error estimates ranged $0.7 \%$ (Method 1) to $0.9 \%$ (Method 2), with no single year/method exceeding 2\%; FRAM's value (8\%) significantly exceeds these estimates. FRAM uses 6\% for legal-marked release error in selective Chinook fisheries. Suvey estimates for this parameter ranged from $24-37 \%$, with a mean of $28 \%$; VTRs yielded $5 \%$ as an estimate. FRAM models 150 encounters per test fishing boat per month. The average number of actual test fishing encounters per area and month was 157 in Area 5 and 71 in Area 6.

## Method 1 versus Method 2

Though it is impossible to know with certainty the true number of Chinook salmon encountered in a particular fishery, both Method 1 and Method 2 have the potential to yield biased estimates. For this reason, it may be more productive to define the set of conditions under which one method is expected to yield better (i.e., less biased) estimates than the other and/or determine defensible means for adjusting for measurable biases when they occur.

## Length and Duration of Monitoring

Very little additional knowledge was gained after the first three years of monitoring and evaluation. Since catch per effort (C/f) can be computed from baseline sampling, it could be
used along with relative changes in effort to monitor gross changes in the fishery in lieu of the intensive sampling that has occurred to date.

## Conservation Objectives

## The estimated mortalities of unmarked Chinook were less than predicted in FRAM models used during the pre-season planning process for every year of the fishery.

## OVERALL RECOMMENDATIONS

- With the existing sampling program and Methods 1 and 2 as starting points, WDFW and tribal technical staff should work towards a mutually agreeable encounters and mortalities estimation framework.
- The dockside interview process should be modified to quantify the extent of intentional legal-marked Chinook release activity for the entire recreational fleet.
- In areas with sufficient test boat samples, VTRs add relatively little additional information. However, VTRs can provide useful information on mark rate and sublegalsize to legal-size ratios when test fishing is not conducted.
- We recommend utilizing the most efficient method of catching fish on test boats in order to boost sample size and increase precision.
- With the high mark rate of legal-size Chinook (40-60\%), the low rate of sublegal encounters, the absence of local stock CWTs, and the low number of fish released per harvested fish, the Area 6 fishery would be a very good choice for expanded angler opportunity.
- We recommend a maximum of 3 years of monitoring for short-duration (less than 3 months) selective fisheries unless inter-year variation suggests additional years of monitoring are necessary.
- Adjust the FRAM input parameter for unmarked retention error to a value of $2 \%$.
- Defer a decision on a new value for mark release error pending resolution on methodology.
- Continue to model 150 Chinook encounters per test fishing boat and month if necessary.
- No FRAM change to model sublegal retention is proposed.

## INTRODUCTION

Five years of the Area 5 and 6 "pilot" mark-selective Chinook salmon (Oncorhynchus tshawytscha) fishery, including the monitoring/sampling programs needed for evaluation of the fishery, have been completed. This multi-year report has been produced to review achievement of the purpose for implementing pilot selective Chinook fisheries in Areas 5 and 6 during the 2003 through 2007 seasons. The pilot fishery purpose is stated in the State-Tribal agreement documents (Northwest Treaty Tribes and the Washington Department of Fish and Wildlife 2007):
"The purpose of the 'pilot' fishery is to collect information necessary to enable evaluation and planning of potential future mark-selective fisheries. The 'pilot' fishery provides a basis for determining if the data needed to estimate critical parameters can be collected and if the sample sizes needed to produce these estimates with agreed levels of precision can be realistically obtained."

These mark-selective fisheries were planned making assumptions about the performance of the fishery and how the fishery will affect wild (unmarked) and hatchery (marked) Chinook salmon. For example, the total number of marked and unmarked Chinook salmon encountered in these fisheries was estimated during the pre-season planning process using the Chinook FRAM and assumptions about fish abundance and angler effort levels. The sampling and monitoring programs in place for the "pilot" fisheries will aid verification of these assumptions. More fundamentally, results of the programs will be used to determine if the data needed to provide usable estimates of critical parameters can be collected.

These monitoring and sampling programs were designed to collect and provide data to estimate the following parameters, as listed in the State-Tribal agreement documents (Northwest Treaty Tribes and the Washington Department of Fish and Wildlife 2007), which we will evaluate in this multi-year report:

- the mark rate in the fishery: marked and unmarked encounters estimated by both onwater and shore-based programs;
- the incidence of partial adipose clips: estimated by both shore-based and on-water programs;
- the number of fish retained or landed: marked and unmarked fish estimated using a shorebased program, including CWT and scale-age sampling;
- the number of unmarked fish released: estimated by shore-based and on-water programs;
- the number of unmarked fish retained: estimated by a shore-based program and compared to enforcement program estimates;
- the number of marked fish released: estimated by a shore-based program in conjunction with on-water mark rate encounter estimates;
- the number of the Chinook encounters that are of sub-legal size: estimated by shorebased and on-water programs;
- the stock composition of the mortalities: estimated by CWT recoveries via dockside sampling and DNA samples in the test fishery [note: the DNA samples have been collected but not analyzed for stock composition];
- estimates of marked and unmarked mortalities of double-index tagged (DIT) and other CWT stocks.

With the exception of partial adipose-clip incidence (bullet 2) and DNA-based stock composition (bullet 8), we evaluate each of the above parameters in this multi-year review document. Additionally, we present analyses of several other parameters of significance to the evaluation and future management of selective Chinook fisheries.

Mark-selective fisheries provide fishery managers a means of reducing harvest rates on unmarked, mostly wild stocks, relative to alternative, non-selective fisheries. This conservation benefit of mark-selective fisheries may be offset by reduced accuracy or precision with estimates of mortalities on wild fish. In non-selective fisheries, much of the mortality on unmarked or wild stocks can be estimated using information collected by directly surveying the landed catch (creel or catch record system and some type of dock-side sampling program). However, fish that die in the process of being caught and released, incidental mortalities, must be estimated indirectly with information provided by programs designed to estimate the number of fish encountered and released. The principle focus of "Pilot" mark-selective fisheries recently implemented by Comanager agreement in Puget Sound for Chinook salmon is to evaluate new and alternative programs designed specifically for this purpose.

Another source of uncertainty introduced by mark-selective fisheries is the increased reliance on assumptions about the proportion of released fish that are expected to die. The effect of uncertainty about release mortality rates on fishery mortality estimates is not a subject of this report.

This report was completed by WDFW, while incorporating extensive review and input from the Tribes. We review and analyze results of the monitoring/sampling program to evaluate if the intended objectives of the first five years of pilot fisheries in Areas 5 and 6 have been achieved. These objectives include: 1) collect information necessary to enable evaluation and planning of future potential Chinook mark-selective fisheries; and 2) determine if the data needed to estimate critical parameters can be collected and if the sample sizes needed to produce these estimates with agreed levels of precision can be realistically obtained. The intent is to complete this review and evaluation in a timely manner to inform managers as they plan the 2008 season.

Our multi-year report contains two sections, each of which addresses separate aspects of the Areas 5 and 6 selective fisheries. In Section I, we present the modeling, sampling, and estimation methods that were employed in our evaluation of these two fisheries; provide resulting estimates of key fishery parameters; and discuss their patterns and significance on both a within- and between- area and season basis. In Section II, we address four topical questions relating to how the sampling, estimation, and modeling of the Areas 5 and 6 fisheries has been conducted over the past five seasons. These questions and their associated analyses are
presented and discussed in a manner that aims facilitate discussions for improved selective fisheries monitoring in the future.

## STUDY AREA

During the summers of 2003 through 2007, a selective Chinook recreational fishery was implemented in waters of the Strait of Juan de Fuca including Marine Area 5 and the western portion of Marine Area 6 (Figure 1). Marine Areas 5 and 6 (hereafter: Areas 5 and 6) are located in Washington waters of the Strait of Juan de Fuca, running from the Sekiu River easterly to Low Point, and from Low Point to approximately Whidbey Island, respectively (Figure 1). Area 5 has public access only at Sekiu/Clallam Bay and at Pillar Point. Although empirical data has not been collected, Area 5 is generally regarded as a "destination" location, meaning that anglers tend to make multiple day trips there due to the distance from any large city. Area 6 on the other hand, has public access throughout the length of the area, including Whiskey Creek, Freshwater Bay, Ediz Hook, Port Angeles, Sequim, and Port Townsend. Area 6 attracts relatively few multiple day trips and is generally fished by local anglers living near Sequim and Port Angeles, or by anglers trailering their boat for the day from other parts of Puget Sound. Chinook selective fishing in Area 6 was open only from Low Point easterly to Ediz Hook because the eastern portion of Area 6 has many more boat ramps and other access points, and would have required substantially more sampling effort to obtain precise estimates of harvest and effort. Additional closures to help achieve fishery objectives were established: 1) in the eastern half of Marine Area $4 ; 2)$ near the mouths of the Sekiu and Hoko rivers; 3) near the mouth of the Elwha River; and 4) in Port Angeles Harbor.

Figure 1. Map of Marine Catch Areas 5 and 6 in Puget Sound, where the selective Chinook fishery occurred during 2003 through 2007.

## FISHERIES OVERVIEW

Each year the fishery was scheduled to start in early July and run continuously until either the quota of harvested Chinook was attained or a set number of days was reached, whichever came first (Table 1). Anglers were allowed to retain two marked (adipose fin clipped) Chinook salmon $\geq 22 "(56 \mathrm{~cm})$ as part of their daily limit, and were required to immediately release, unharmed, any unmarked Chinook caught. During the Chinook Selective Fishery anglers were also allowed to retain pink (O. gorbuscha), sockeye (O. nerka), and marked hatchery coho (O. kisutch) salmon.

Table 1. Dates and Chinook harvest quotas for the Areas 5 and 6 selective Chinook fishery, 2003 through 2007. The fishery closed upon reaching the scheduled closing date or when the quota was harvested, whichever came first.

| Year | Opening Date | Scheduled Closing Date | Maximum Possible Days Open | Quota |
| :---: | :---: | :---: | :---: | :---: |
| 2003 | July 5 | August 14 | 41 | 3,500 |
| 2004 | July 1 | August 10 | 41 | 3,500 |
| 2005 | July 1 | August 10 | 41 | 3,500 |
| 2006 | July 1 | August 31 | 62 | 3,500 |
| 2007 | July 1 | August 31 | 62 | 4,000 |

## SECTION I: WITHIN AND BETWEEN-YEAR PATTERNS IN FISHERY PARAMETERS

## METHODS

Overview
From 2003 through 2007, we implemented separate sampling programs in Areas 5 and 6 (Figure 1) in order to collect the data necessary to estimate critical fishery parameters. Preliminary analyses of the 2003 through 2006 fisheries were completed and are reported by Thiesfeld and Hagen-Breaux (2005a, 2005b), and WDFW (2005, 2006, 2007a). For each area, the general study design was built around Murthy's population-total estimator (Murthy 1957, Cochran 1977) and was focused specifically on obtaining daily estimates of total catch and total effort. The program incorporated comprehensive and complementary data collection strategies, including: 1) dockside-based angler interviews and catch sampling; 2) on-the-water total (instantaneous) effort surveys; 3 ) test fishing; and 4) voluntary reports of completed trips provided by private anglers (Figure 2).

Figure 2. Conceptual diagram of the monitoring plan implemented to estimate fishery impacts in Areas 5 and 6 for their 2003-2007 mark-selective Chinook seasons. Circles represent sampling programs, dashed boxes represent key parameters that are estimated using data from a given program (i.e., the data necessary for estimating other parameters, e.g., age composition, are collected but not depicted), and solid boxes depict bottom-line quantities estimated using combined programs. As depicted, 'Encounters' includes both harvested and released Chinook salmon.

## Dockside Sampling

Catch and effort were estimated by creel surveys following the procedures detailed in WDF and NWIFC (1992), with the exception that expansion factors (i.e., cluster sizes or "size measures") were determined in-season, rather than using previously determined effort levels. Thus, our dockside angler-interview efforts followed a two-stage stratified cluster sample design. At the first stage, we selected sample days from all available selective-fishery days from two timebased strata; at the second stage, we randomly selected (with probability proportional to size, PPS) fishery-access points (i.e., public ramps, boathouses, etc.) at which we interviewed anglers (the clusters) to collect data about their fishing trips and to sample their catch.

## Sampling Strata and Shifts

In order to maximize the accuracy and precision of our estimates of fishery-related parameters, we incorporated temporal stratification into our sample design. We divided each week into "weekday" (Monday through Thursday; low effort days) and "weekend" (Friday, Saturday, and Sunday; moderate to high effort days) sample strata; we scheduled two randomly selected days in the Monday-Thursday (weekday) stratum and all weekend days (Friday, Saturday, and Sunday) for dockside sampling. On selected sample days and at selected access sites (described
below), sample shifts lasted from dawn until dark so that samplers could intercept all boats and anglers departing the fishery from that site.

## Sample Frame and Site Selection

Before the start of the fishery, we determined our access-site sample frame based on a compilation of all known, publicly accessible (i.e., sampleable), and moderate-to-high effort boat-launch facilities present in Areas 5 and 6. Access sites with low effort, as determined from boat survey data (see "Boat surveys" section below), were excluded from our sample frame. Two access sites were randomly chosen for sampling on each scheduled sample day using a weighted random site-selection process. A computer program developed by Mark Hino, WDFW Fish and Wildlife Biologist, was used to select two sites for each sampling day based on their "size" or "weight" (i.e., the proportion of angler effort contained in the sample frame that on average uses the site based on boat-survey estimates; Murthy 1957, Cochran 1977) according to a PPS-without-replacement algorithm. The "size" estimates (proportion of effort for each site) used during the site selection was based on the effort distribution obtained from boat surveys (described below).

## Dockside Interview Procedures

On each day scheduled for sampling during the selective Chinook fisheries, 1-3 ramp samplers (depending on day length, anticipated effort, etc.) were stationed at each selected access site so that they could interview all anglers as they exited the fishery at these locations. Samplers interviewed anglers and collected data on trip duration and encounter (fish retained and/or released) composition, by species and mark status (unmarked vs. marked or adipose-fin clipped; Chinook and coho salmon only); data on the size-status (i.e., legal or sublegal) of released fish were not collected. In addition, samplers inspected all landed Chinook and coho salmon for the presence of coded-wire tags (CWT) using wand CWT detectors and snouts were collected from all fish containing CWTs. Biological measurements (fork lengths, total lengths) and scale samples were also acquired from a sample of landed Chinook. Total lengths were not collected in 2003 and 2004. Fork lengths were converted to total lengths for analysis using the recommended equations presented in Conrad and Gutmann (1996). In addition, samplers logged counts of all anglers and fish exiting the fishery at sampled access sites and any anglers/boats missed were counted and recorded on sampling forms (i.e., for use during the estimation process).

Additionally, given their daily exposure to anglers participating in the selective Chinook fisheries, dockside samplers educated anglers about regulations and the proper release of unmarked or sublegal Chinook salmon when time allowed. They relayed that mark-selective regulations permitted the retention of two marked (adipose fin-clipped) Chinook salmon >22 in ( $>56 \mathrm{~cm}$ ) per day and required the immediate release (outside the gunwales and without boating) of all unmarked Chinook encountered. Dockside samplers also offered anglers a "dehooker" with an accompanying pamphlet which described proper dehooker use, selective fisheries in general, and accurate species/mark-status (i.e., adipose-fin clipped vs. unmarked) identification. Samplers reminded anglers that in addition to marked Chinook, they could retain other salmon
species (no minimum size) during the selective Chinook season, under a total combined daily limit of two salmon.

Finally, to help shape test-fishing efforts (described below under "Test Fishing") on an in-season basis, dockside samplers collected data on the type and frequency of fishing methods employed by the private fleet during angling excursions. Specifically, samplers inquired about and recorded the predominant (based on time) angling method that was employed for boats that successfully encountered Chinook. Responses were recorded on the sampling form according to the following five fishing method categories: 1) weight and bait (i.e., mooching or slow trolling with lead and herring/anchovy); 2) downrigger trolling (using hardware, bait, or both in combination); 3) jigging (i.e., drifting and jerking pole up and down, e.g., using Buzz Bombs, Point Wilson Darts, or Crippled Herring); 4) diver trolling (e.g., trolling with a Deep Six or a Pink Lady using hardware, bait, or both in combination); and 5) other methods (e.g., fly fishing). Based on these responses, test fishers fished using the same methods in approximately the same proportions as the recreational fleet (see WDFW 2007b and 2007c).

## Boat Surveys

In order to obtain precise and up-to-date size measures (i.e., for site selection and within-frame total estimation) and out-of-frame effort proportion estimates (i.e., for expanding catch and effort estimates for our sample frame to fishery-total values), we incorporated on-the-water effort surveys (boat surveys) to estimate the proportion of angler effort originating from different fishery-access points. Boat surveys were comprehensive in space (i.e., they spanned the entirety of each Marine Area) and were assumed to be instantaneous in time. To maximize angler contact, surveys were scheduled during periods of peak fishing effort.
While traversing each area, the boat-survey samplers attempted to intercept all actively fishing boats, and asked occupants how many anglers were on board and where they intended to tie up or exit the fishery upon completing their trip. We excluded non-fishing vessels and vessels that were under way from our sample.

We conducted a minimum of two and an average of four boat surveys per month in each area, separately. Additional boat surveys were conducted whenever significant changes in effort patterns were anticipated (e.g., if access sites or fisheries in adjacent marine areas opened or closed). Using the most recent boat-survey results, we calculated the size measures of sites contained in the sample frames for each week during the selective fishery season.

## Test Fishing

In order to obtain accurate estimates of the size (legal or sublegal) and mark-status (marked or unmarked) composition of the pool of Chinook salmon encountered by anglers in the Areas 5 and 6 fisheries, we operated 2 WDFW-staffed test boats (one in each area) for the entirety of the 2003 through 2007 seasons. Each test boat had a crew consisting of two WDFW technicians, each of which fished with a single rod. Test fishers fished approximately five days per week (Monday through Friday) during each season, and assisted with other tasks if weather precluded fishing. Test fishers were also involved with on-the-water boat surveys.

Test-boat crews focused their fishing efforts at locations in both areas that optimized their overall encounter rate (i.e., to increase precision) and mirrored choices made by the at-large private fleet. Starting in 2004, to better ensure the accuracy of test-fishing data, samplers fished for Chinook with similar methods and gear as the recreational fleet. We prescribed the proportions of time that the test boats should spend fishing with different methods based on dockside interview results from the preceding week (described above under "Dockside Interview Procedures"). In both areas, downriggers were the predominate method used by anglers to encounter Chinook. For each test-boat hook-up, the encounter number, time sampled, species, mark status, and DNA vial number (if applicable) was recorded. Care was taken to handle all fish as gently as possible. Chinook that were not lost via "drop off" were brought on board and measured in a cotton mesh net. Samplers recorded the fork length, total length (except in 2003 and 2004), and mark status, and collected three scales for each Chinook brought on board. In 2003 and 2004, fork lengths were converted to total lengths for analysis using the recommended equations presented in Conrad and Gutmann (1996). Scales were collected following procedures outlined by the International North Pacific Fisheries Commission (1963), to enable age analysis of Chinook encountered in the fishery.

In addition, samplers used scissors to remove a $1-\mathrm{cm}^{2}$ section of tissue from the dorsal fin or the caudal fin of all Chinook brought on board, and then placed the sample in a solution of ethanol. Tissue samples were collected to obtain DNA for future genetic analysis of stock composition (i.e., DNA-based stock composition estimates are presently unavailable). Data collected by the two test boats were used to estimate the size/mark-status composition of Chinook encounters and legal mark rates (i.e., $\%$ of legal-sized fish that were marked) in the recreational fishery. These size/mark-status group (legal-marked, legal-unmarked, sublegal-marked, sublegal-unmarked) proportions were ultimately used to apportion total Chinook encounters to these same classes for use in fishery-impact estimation (Appendix A). In contrast to the annual reports where these proportions were weighted by catch, in this document we use unweighted season-long proportions (see Appendix B for discussion of this methodology change). In addition, size distributions (i.e., length-frequency histograms) were derived from test-fishing data for both marked and unmarked groups, separately, for each year.

## Voluntary Trip Reports

Additional data on the size/mark-status composition and mark rates of Chinook encountered during the fisheries were obtained from anglers who submitted Voluntary Trip Reports (VTRs) in each season. In 2003, VTRs were distributed to any angler that expressed interest. Starting in 2005, participating anglers were asked to attend a class lasting from 30-45 minutes during which they received information on salmon species identification and became familiar with the VTR forms, what data to collect, how to fill out the forms, and how to turn in the forms. On VTR forms, anglers were asked to record the date, number of anglers, target species, CRC Area, encountered species (if they positively identified the fish), including each Chinook or coho salmon, whether the fish was kept or released, total length to the nearest $1 / 8^{\text {th }}$ in $(0.3 \mathrm{~cm})$, and whether the fish was adipose fin-clipped or not clipped. Based on this information, we estimated the mark rate of legal and sublegal Chinook and then compared these results with test-fishing data and VTRs. In addition, we estimated the legal-marked release rate where possible, as the magnitude of this quantity bears directly on the accuracy of "Method-2" estimates of total
encounters. Due to self-selection and non-response issues associated with sampling anglers using VTRs in Areas 5 and 6, however, this estimate (among others obtained from VTRs) may be biased relative to the entire private fleet.

## Estimation Methods

## Pre-season Fishery Modeling with FRAM

The Fishery Regulation Assessment Model (FRAM) was used to estimate fishing impacts in the selective Chinook fisheries for preseason assessment purposes. In contrast to our fisherysampling program, FRAM evaluations are conducted using both areas combined (i.e., it is parameterized for modeling Areas 5 and 6 as a single unit). Based on the set of fishery parameters and stock abundances input to the model, FRAM provides estimates of landed catch, total mortality, and the number of Chinook encountered (i.e. brought to the boat), by stock and age. For each year, FRAM inputs for this fishery include the mark-selective fishery landed catch quota ( 3,500 in 2003-06, 4,000 in 2007) and several fishery related parameters (Table 2). FRAM contains three specific selective fishery parameters:

1. "Marked Release Error" is the proportion of the legal-marked Chinook encountered that are released,
2. "Unmark Retention Error" is the proportion of legal-unmarked Chinook encounters that are improperly retained.
3. "Selective Fishery Release Mortality" (sfm) is the release mortality on legal size Chinook.

Two other fishery-related mortality rates input to FRAM, "Release Mortality" and "Drop-off Mortality", are used in non-selective fisheries, as well. Although not a FRAM input per se, the algorithms in FRAM do not account for retention of sublegal fish; i.e. sublegal retention error is zero.

FRAM fishery input parameters were discussed and accepted by state and tribal co-managers prior to the annual season setting process. The values used in FRAM for the 2003-07 Areas 5 and 6 selective Chinook fishery are shown in Table 2. The same rates were used in all years These rates are based on a combination of studies, anecdotal reports, or simply as an agreed-to value for modeling purposes (e.g. Drop-off). The selective fishery parameters (Marked Release Error and Unmarked Retention Error) were not developed from specific studies for this fishery.

Table 2. Input parameter values used in FRAM pre-season fishery modeling for the combined Areas 5 and 6 selective Chinook fisheries set for the 2003 through 2007 seasons.

| Parameter | Value | Applies to | Notes |
| :--- | :--- | :--- | :--- |
| Marked Release Error ${ }^{1 /}$ <br> Unmarked Retention Error ${ }^{1 /}$ | 0.06 | Legal-marked encounters |  |
|  | 0.08 | Legal-unmarked <br> encounters |  |

## Creel-based Estimates of Catch, Releases, and Effort

Using data acquired from sampled access sites, we estimated total daily encounters (by group, according to the classes enumerated during dockside sampling; e.g., retained-marked Chinook, released unmarked Chinook, retained-marked coho, etc.) and effort for anglers accessing the fishery from all sites contained in our Area-5 and Area-6 sample frames, separately, using dockside counts and the size measures of sites sampled on scheduled sample days. Angler trips and anglers are used interchangeably throughout the document to represent effort. We then expanded dockside-frame estimates to daily totals based on the proportion of total fishing effort originating from access sites that were not contained in our sample frame (Figure 2). Finally, we expanded daily estimates to stratum (weekday vs. weekend), weekly, monthly, and ultimately season totals. We used a Microsoft Access application developed by Kurt Reidinger (WDFW Fish and Wildlife Biologist) to enter sample data, generate expanded estimates, and produce appropriate variances for all sampled strata.

Sample-frame total catch and effort were estimated using Murthy's total estimator (Murthy 1957; Cochran 1977):

$$
\begin{equation*}
\hat{Y}=\frac{\left[\left(1-P_{2}\right) *\left(E_{1} / P_{1}\right)+\left(1-P_{1}\right) *\left(E_{2} / P_{2}\right)\right]}{\left(2-P_{1}-P_{2}\right)} \tag{1}
\end{equation*}
$$

where:
$\hat{Y}=$ daily estimator (e.g., anglers, marked Chinook retained, etc.),
$P=$ proportion of effort (size measure) at sites $l$ and 2 , and
$E=$ sampled (observed) count at site 1 and 2.
The variance around sample-frame totals was estimated according to:

$$
V(\hat{Y})=\frac{\left(1-P_{1}\right)\left(1-P_{2}\right)\left(1-P_{1}-P_{2}\right)}{\left(2-P_{1}-P_{2}\right)^{2}} *\left[\frac{E_{1}}{P_{1}}-\frac{E_{2}}{P_{2}}\right]^{2}
$$

All accounting for missed boats/anglers was done within WDFW's Microsoft Access catchestimate system; using the average catch-per-boat estimated for a given site-day combination and the number of missed boats logged on forms, an estimate of unobserved catch was incorporated into the sample-frame totals. An analogous computation was made to account for the number of anglers not interviewed from the missed boats.

Finally, we expanded daily catch and effort estimates generated for our sample frame to fishery totals based on the proportion of effort (estimated from boat-survey data) that originated from out-of-frame access sites:

$$
\begin{equation*}
\hat{Y}_{a d j}=\frac{\hat{Y}}{\left(1-\hat{p}_{\text {nonsampled }}\right)}=\frac{\hat{Y}}{\hat{q}} \tag{3}
\end{equation*}
$$

where:

$$
\begin{aligned}
\hat{Y}_{a d j}= & \text { daily estimator after expansion by an estimate of the proportion of effort that } \\
& \text { originated from the non-sampled access sites, and } \\
\hat{q} \quad= & \text { expansion factor to account for the proportion of effort originating from out-of- } \\
& \text { frame access sites, } \hat{p}_{\text {nonsampled }} \text { (i.e., sites not included in the sample frame and } \\
& \text { therefore never sampled). }
\end{aligned}
$$

The variance of expanded total estimates was approximated as:

$$
\begin{equation*}
V\left(\hat{Y}_{a d j}\right)=\hat{Y}_{a d j}{ }^{2} *\left[\frac{\hat{V}(\hat{Y})}{\hat{Y}^{2}}+\frac{\hat{V}(\hat{q})}{\hat{q}^{2}}\right] \tag{4}
\end{equation*}
$$

The reliability of estimates of Chinook landings, releases, and/or effort obtained using the abovedescribed approach depends on the validity of the following four assumptions:

- Boat surveys provide unbiased estimates of access-site size measures and out-offrame effort proportions (Assumption 1);
- Relative angling effort originating from a particular access site (i.e., its size measure) is proportional to total catch landed at that site (Assumption 2);
- All anglers exiting the fishery at sampled site are interviewed and they accurately report all salmon caught and kept or released (if boats are missed they are counted and catch and effort estimates are expanded appropriately (Assumption 3); and
- Catch per unit effort does not differ significantly between in-frame and out-of-frame sites (Assumption 4).

Although Conrad and Alexandersdottir (1993) assessed the effects of Assumption 2 violations on estimates of catch and effort for Puget Sound salmon fisheries, Assumptions 1, 3, and 4, have not been explicitly evaluated to date (Appendix C).

A slight change to previously reported estimates was undertaken for this multi-year analysis. We pursued an additional estimation step to apportion a percent of unidentified salmon released to the released-Chinook category; we did this on a monthly time step according to the composition of known-species salmon releases (i.e., based on expanded Murthy estimates generated from interview data). This quantity-apportioned unidentified salmon ( $\hat{N}_{\text {AUS }}$ ) hereafter-is derived from estimated quantities [unidentified salmon, $\hat{N}_{U S}$, and the proportion of Chinook in estimated releases $\left(\hat{p}_{\text {Chin }}=\hat{N}_{\text {Chin }} / \sum \hat{N}_{I D^{\prime} d-\text { salmon }}\right)$ ], and has an estimator (5) and variance (6) of:

$$
\begin{gather*}
\hat{N}_{A U S}=\hat{N}_{U S} * \hat{p}_{C h i n}  \tag{5}\\
V\left(\hat{N}_{A U S}\right)=V\left(\hat{N}_{U S}\right) * \hat{p}_{C h i n}^{2}+\hat{N}_{U S}^{2} * V\left(\hat{p}_{\text {Chin }}\right)-V\left(\hat{N}_{U S}\right) * V\left(\hat{p}_{C h i n}\right),
\end{gather*}
$$

where, also based on estimates:

$$
\begin{equation*}
V\left(\hat{p}_{\text {Chin }}\right)=\hat{p}_{\text {Chin }}{ }^{2} *\left[\frac{V\left(\hat{N}_{\text {Chin }}\right)}{\hat{N}_{\text {Chin }}{ }^{2}}+\frac{V\left(\hat{N}_{\text {ID'd-salmon }}{ }^{2}\right)}{\hat{N}_{\text {ID'd-salmon }}{ }^{2}}\right]+V\left(\hat{N}_{\text {Chin }}\right) *\left[\frac{V\left(\hat{N}_{\text {ID'd-salmon }}\right)}{\hat{N}_{\text {ID'd-salmon }}{ }^{4}}\right] \tag{7}
\end{equation*}
$$

## Total Chinook Encounters Estimation: Methods 1 and 2

We estimated the total number of Chinook encountered during the selective Chinook fisheries during each season using two different estimation approaches ("Method 1" and "Method 2"). Under Method 1 (the harvest-plus-reported-releases method), we simply summed Murthy estimates and variances for all Chinook encounter sub-categories (i.e., retained marked and unmarked Chinook; released marked, unmarked, and unknown-mark-status Chinook; and apportioned unidentified salmon releases), which were estimated according to the process outlined above, to estimate total Chinook encounters. Relative to Method 2, the reliability of Method-1 estimates depends on how accurately anglers recall and report the number of salmon released, and their mark status, during their trips. Past studies suggest that there is a tendency for over-reporting of releases in Puget Sound and other fisheries (e.g., Noviello 1998; Sullivan 2003), the magnitude of this "prestige bias" has not been quantified for selective Chinook fisheries.

Under Method-2 (the harvest-only method), we estimated total Chinook encounters by combining fishery-total estimates of retained legal-marked Chinook (outlined above) with testfishery data on the size/mark-status composition of the pool of encountered Chinook salmon. Relative to Method 1, the reliability of Method-2 estimates depends on the degree to which anglers release marked legal-size Chinook. Specifically, we estimated total Chinook encounters ( $\hat{E}_{\text {tot }}$ ) for each month, then summed these to get a season total by expanding creel-based
estimates of legal-marked Chinook retention $\left(\hat{N}_{L M}\right)$ by the test-fishing estimate of the legalmarked proportion in the encountered Chinook pool ( $\hat{p}_{L M}$ ) (see Appendix A for variance details):

$$
\begin{equation*}
\hat{E}_{\text {tot }}=\hat{N}_{L M} / \hat{p}_{L M} \tag{8}
\end{equation*}
$$

Thus, in addition to the usual assumptions affecting the accuracy of Murthy-based estimates of legal-marked Chinook retention (Assumptions 1-4), the Method-2 estimation approach also assumes:

- Anglers accurately identify and retain all legal-marked Chinook encountered during fishing trips (Assumption 5). If anglers intentionally (e.g., releasing legal-marked Chinook in order to catch and retain larger individuals) or unintentionally (e.g., measurement error) release legal-marked Chinook, Method-2 estimates will have a negative expected bias (relative to the true, unknown value).
- The extent to which test-boat samplers accurately mimic the private fleet in angling behavior also affects the accuracy of Method-2 estimates (i.e., the size/mark-status composition experienced by the private fleet is identical to that seen in the test fishery; Assumption 6).

The performance of Method-1 and -2 estimators (and the associated validity of assumptions) under the range of fishery conditions present in Areas 5 and 6 will be addressed in detail in Section II of this report.

## Fishery Impacts (Encounters and Mortalities) by Size/Mark-Status Group

Method-1 and-2 encounter estimates were decomposed to size/mark-status categories using a combination of creel estimates, test-fishery data (size/mark status composition), and dockside observations of landed catch (for apportioning retained-marked and -unmarked fish to size classes). While this and the subsequent mortality-estimation routine are detailed in Appendix A, we briefly describe the process here. For both Method-1 and -2 estimates (separately), we apportioned total Chinook encounters to the four size/mark-status categories of legal-marked (LM), sublegal-marked (SM), legal-unmarked (LU), and sublegal-unmarked (SU) based on the composition of test-boat encounters; thus, Assumption 6 (i.e., similar encounter composition for the test boat and private fleet) also applies to our mortality estimation scheme. We then estimated total release mortality due to each area (Areas 5 and 6) and year's (2003-2007) selective fishery by applying size-specific mortality rates to release estimates for the four Chinook size/mark-status classes (LM, LU, SM, and SU). We applied a release mortality rate of $15 \%$ to LM and LU (i.e., $10 \%$ release plus a drop-off mortality approximated as $5 \%$ of legal-size encounters) and $20 \%$ to SM and SU encounter estimates, respectively, for direct comparison to FRAM. We then added retention mortality estimates (i.e., harvest) for each size/mark-status group to release mortality estimate for that same group to obtain total class-specific mortality. Mortalities (and their variances) were calculated on a season-total basis.

Finally, we pooled encounter and mortality estimates for Areas 5 and 6 and compared these Area- 5 and 6 composite values to pre-season modeled (FRAM) encounters and mortalities, for each size and mark status category, and for each year separately. Further, given that Method-1 and -2 encounter estimates are likely to include some degree of bias (assumed positive and negative, respectively) relative to the true number of Chinook encountered in Areas 5 and 6 during each season, we contrasted FRAM predictions with the ranges bounded by the two estimates. Though our FRAM (predicted) versus observed (i.e., post-season estimates) comparisons are qualitative in nature, we present the $95 \%$ confidence intervals associated with observed estimates to provide perspective on statistical uncertainty about differences. It should be noted, however, that these CIs do not incorporate uncertainty due to the release mortality rates applied (i.e., $s f m_{\mathrm{L}}$ and $s f m_{\mathrm{S}}$ in Appendix C, both are assumed constants) and therefore the intervals are underestimated.

## Coded-Wire Tagged (CWT) Chinook Impacts

To understand the potential effects of the selective Chinook fisheries on CWT-based cohortreconstruction efforts, we estimated the number of unmarked-tagged Chinook mortalities that occurred during the course of the selective fishery for each year. Thus, we acquired information on recovered CWT's for all double index tag (DIT) groups encountered and then applied the methods described by WDFW (2002) to estimate the number of unmarked-DIT Chinook that were encountered and the number of these fish that subsequently died due to handling and release impacts.

The approach used to estimate unmarked-DIT mortalities in the selective fishery was developed by the Selective Fisheries Evaluation Committee - Analysis Work Group (SFEC-AWG 2002) and were evaluated by a workgroup consisting of State and Tribal biologists and statisticians, including members of SFEC-AWG (Joint Coho DIT Analysis Workgroup 2003). Given our interest in the effects of mark-selective fisheries on the CWT program, we used a selective fishery mortality rate ( $s f m$ ) of $10 \%$ to estimate unmarked-DIT mortalities in our analysis; this is the same release mortality rate used in FRAM legal-Chinook model runs, less drop-off mortality ( $5 \%$ of legal encounters). We used $10 \%$ instead of $15 \%$ (we apply above to all legal releases), however, because unseen drop-off mortality is theoretically equivalent for marked and unmarked fish and present in both selective and non-selective recreational Chinook fisheries. Thus, our estimates of unmarked-DIT mortalities are analogous to impacts in excess of those that would occur under non-selective regulations.

For each year, we estimated encounters and mortalities for each recovered DIT individually and then summed estimates for each hatchery, brood year, and area, because the sampling rate changed throughout the fishery and was different between areas (WDFW 2002). Thus, the estimated number of unmarked mortalities was calculated as:

$$
\begin{equation*}
\hat{U}_{a}^{M S F}=\lambda^{R E L} \hat{M}_{a}^{M S F}{ }^{\text {MSm }} \tag{9}
\end{equation*}
$$

with associated variance:

$$
\begin{equation*}
\operatorname{Var}\left(\hat{U}_{a}^{M S F}\right) \approx\left(\lambda^{R E L}\right)^{2} s f m^{2} \hat{M}_{a}^{M S F} \frac{1-s}{s} . \tag{10}
\end{equation*}
$$

where:

$$
\begin{aligned}
& s f m \quad=\text { selective fishing mortality rate ( } 10 \% \text {, excludes drop-off mortality), } \\
& U_{a, i}{ }^{M S F}=\operatorname{aged} a \text { unmarked DIT mortalities from stock } i \text { in the selective fishery, } \\
& M_{a, i}{ }^{\text {SSF }}=\text { aged } a \text { marked DIT mortalities from stock } i \text { in the selective fishery, } \\
& s \quad=\text { sampling rate of the catch, } \\
& \lambda^{R E L}=\text { unmarked to marked ratio at release for fish in a DIT group, and } \\
& \operatorname{Var}\left(U_{a, i}{ }^{M S F}\right)=\text { variance of } U_{a, i}{ }^{\text {MSF }} \text {. }
\end{aligned}
$$

In addition to estimating unmarked-DIT mortalities, we pooled all CWTs (DIT and otherwise) recovered during the fishery and, based on this total, report the proportional contribution (unexpanded recoveries) of different hatcheries to the total Chinook harvest.

## SECTION I: RESULTS

## Pre-Season FRAM Results

Preseason FRAM run results for the combined Areas 5 and 6 mark-selective Chinook fishery for 2003 through 2007 are shown in Table 3. Areas 5 and 6 are treated as one fishery in FRAM; consequently separate estimates for each Area are not produced. These estimates calculated in FRAM incorporate all fishery inputs and marked and unmarked stock abundances for each year. A specialized output from FRAM called the Selective Fishery Report contains more detailed results by stock and age (Appendix D).

## Creel Survey Results

Over the 5 years of the study, the fishery has lasted from 30 to 49 days (Figure 3). During 2006 and 2007, the fishery was closed for assessment purposes and then was re-opened from 1 to 4 days to harvest the remainder of the quota (Table 4). The harvest quota was obtained each year, except in 2005 when catch per angler was extremely low, and consequently 2005 was the only year the scheduled closing date was the actual closing date.

|  | All | 7,562 | 9,475 | 3,532 | 468 | 4,504 | 2,023 |

## Fishing Effort

Total effort ranged between approximately 22,000 and 34,000 angler trips per year (angler trips and anglers are used interchangeably throughout the document; Table 4, Figure 4 and Appendix E). Effort was effected by the length of the season and angler success. The highest effort occurred in 2005, the longest of the 5 seasons at 49 days, and the lowest effort occurred in 2007, the second shortest season at 36 days. The majority of effort was expended in Area 5, ranging from $79 \%$ in 2003 to $88 \%$ in 2005 and 2006 (Table 5). On average, $85 \%$ of the effort occurred in Area 5. The number of anglers per day ranged from 536 per day in 2006 to 831 per day in 2005 (Figure 5).

Figure 4. Total number of angler trips, and $95 \%$ confidence intervals, in the Area 5 and 6 selective Chinook fishery, 2003 through 2007.

Figure 5. Total number of anglers per day participating in the Area 5 and 6 selective Chinook fishery, 2003 through 2007.

## Chinook Encounters: Estimated Harvest and C/F

The number of Chinook harvested ranged from 2,078 in 2005, the year the quota was not achieved, to 4,096 in 2007 (Figure 6 and Appendix F), the year with the highest quota $(4,000)$. In each year the quota was achieved, the estimated harvest was within $5 \%$ of the quota. The average number of Chinook harvested per day ranged from 51 in 2005 to 116 in 2003 (Figure 7). The majority of the Chinook harvest occurred in Area 5, ranging from $72 \%$ in 2003 to $91 \%$ in 2006. On average, $81 \%$ of the Chinook harvest occurred in Area 5.

The number of Chinook released ranged from 6,408 in 2005 to 14,841 in 2003 (Figure 6 and Appendix F). Note that releases in this section do not include any of the "unknown" salmon released. The majority of the Chinook encountered and released occurred in Area 5, ranging from $88 \%$ in 2003 to $96 \%$ in 2006. On average, $91 \%$ of the Chinook released occurred in Area 5. The number of Chinook released for every Chinook harvested declined throughout the fishery, from 4.2 released/harvested in 2003 to 2.1 released/harvested in 2007 (Figure 8). The decline in the ratio of released to harvested Chinook occurred as the mark rate of legal-size Chinook increased from 2003 to 2007 (Figure 9, see "Test Fishing" for mark rates).

Catch (harvested) of Chinook per angler (C/f) ranged from 0.06 in 2005 to 0.19 in 2007 (Figure 10), or 1 harvested Chinook for every 16 anglers in 2005 to 1 for every 5 anglers in 2007. For the 5 years of the fishery, the unweighted average catch per angler was 0.13 or 1 Chinook harvested for every 9 anglers. Catch per angler was higher in Area 6 every year except 2006 (Figure 11). For the 5 years of the fishery, the unweighted average catch per angler was 0.12 in Area 5 and 0.16 in Area 6.

The total harvested catch per unit effort for Chinook, coho and pink combined ranged from 0.18 fish per angler in 2006 to 0.81 fish per angler in 2007 (Figure 12). The number of anglers per day appears to be correlated with total catch per angler and unrelated to catch per angler of any individual species.

Figure 6. Number of Chinook harvested and released, and $95 \%$ confidence intervals, in the Area 5 and 6 selective Chinook fishery, 2003 through 2007. Does not include Chinook that may have been reported as unknown salmon species released.

Figure 12. Number of anglers per day compared to catch per angler (C/f) in the Area 5 and 6 selective Chinook fishery, 2003 through 2007.

## Creel Survey Mark Rates and Size Composition

Based on dockside sampling of landed catch and angler-reported release estimates for known mark-status Chinook (i.e., excluding apportioned unidentified salmon and unknown mark-status categories), mark rates of Chinook were always higher in Area 6 than in Area 5, and mark rates increased from 0.24 in 2003 to 0.45 in 2007 (Table 6). Area and year specific data from which mark rates were calculated are reported in Appendix G. During the 5 years of the fishery, the percentage of harvested Chinook that were unmarked (sublegal-size and legal-size) ranged from $0.14 \%$ in 2004 to $3.03 \%$ in 2005 and 2007 (Table 7).

Table 6. Mark rates of Chinook reported by anglers interviewed during dockside creel surveys in the Area 5 and 6 selective Chinook fishery, 2003-2007.

|  | Creel Survey Mark Rate |  |  |
| :---: | :---: | :---: | :---: |
| Year | Area 5 | Area 6 | Overall |
| 2003 | 0.219 | 0.377 | 0.245 |
| 2004 | 0.255 | 0.341 | 0.265 |
| 2005 | 0.315 | 0.469 | 0.335 |
| 2006 | 0.459 | 0.510 | 0.462 |
| 2007 | 0.441 | 0.543 | 0.454 |

Table 7. Proportion of harvested Chinook observed during dockside creel surveys that were unmarked in the Area 5 and 6 selective Chinook fishery, 2003-2007.

|  | Proportion of Harvest Unmarked |  |  |
| :---: | :---: | :---: | :---: |
| Year | Area 5 | Area 6 | Overall |
| 2003 | 0.021 | 0.023 | 0.022 |
| 2004 | 0.000 | 0.007 | 0.001 |
| 2005 | 0.029 | 0.010 | 0.026 |
| 2006 | 0.005 | 0.024 | 0.007 |
| 2007 | 0.035 | 0.010 | 0.030 |

During the five seasons of dockside-sampling efforts, dockside samplers measured the lengths of 3,517 Chinook. Harvested Chinook were larger in Area 6 than in Area 5 and mean lengths were significantly different between areas each year (Table 8). Between 4 and 7 percent of the harvested Chinook measured were smaller than the 22 -inch minimum size (Table 9). The highest retention of sublegal-size Chinook occurred in Area 5 during 2007 when 10\% of the harvested Chinook were less than the minimum size. Odd-numbered years (2003, 2005 and 2007) had the highest rates of sublegal-size retention error, possibly because anglers may have confused juvenile Chinook as pink salmon. The proportion of measured Chinook that were legal-size and marked ranged from 0.92 to 0.96 for both Areas combined during the 5 years of the fishery (Tables 10 and 11). The proportion of measured Chinook that were unmarked ranged from 0.00 to 0.03 for both Areas combined during the 5 years of the fishery.

## Estimated Releases \& Total Chinook Encounters

Very few fish were reported as unknown salmon released by anglers reporting their catch to dockside samplers. Nonetheless, we apportioned some of these unknown salmon as Chinook based on the percent of the known releases that were Chinook. The total number of fish reclassified from unknown salmon released to released Chinook varied from 31 in 2005 to 328 in 2003 (Table 12). Most of the unknown salmon released were from Area 5. After apportioning these salmon, the total number of Chinook encounters reported by anglers ranged from a low of 8,517 in 2005 to a high of 18,662 in 2003.

Table 12. Estimates of total Chinook encounters from creel surveys in the Area 5 and 6 selective Chinook fishery, 2003-2007, after apportioning unknown releases into species based on their respective percent of known releases.

|  |  | Known Chinook <br> Enounters from Creel | Number of Unknown <br> Releases Apportioned <br> as Chinook | Final Estimated <br> Chinook Encounters <br> from Creel |

## Test Fishery Results

## Fishing Methods and Effort

Over the two areas and five seasons, Area 5 and Area 6 samplers fishing on test boats spent 2,316 hours pursuing Chinook salmon. Test fishing effort and fishing-method details for 2003 through 2006 are summarized in prior post-season reports (Thiesfeld and Hagen-Breaux 2005a, 2005b, WDFW 2005, 2006, 2007a). In terms of effort descriptors used to characterize the angling public, this translates into a total of 772 angler trips (Table 13). Test boat samplers averaged 37 days on the water during each year in Area 5 and 40 days in Area 6 over the five years, and all missed fishing days were due to a combination of inclement weather and/or boatmaintenance issues. During all years and in both Areas, samplers fished predominately using downriggers ( $>69 \%$ in all cases; Figure 13), as this was also the predominant private-fleet fishing mode ( $>53 \%$ in 5 and $>62 \%$ in 6 ). Despite attempting to mimic angler's methods starting in 2004, most of the Chinook caught by test fishing were still caught using downriggers. Over $90 \%$ of the Chinook caught by test fishing were caught on downriggers every year in Area 5 and $100 \%$ in Area 6. Total mortalities attributable to the very extensive test fishing in the Areas 5 and 6 selective Chinook fisheries ranged from a high of 82 in 2003 to a low of 25 in 2007 (Table 13).

Figure 13. Percent of time that test boats fished various gear types compared to the percent of Chinook encountered by gear type by anglers in the Area 5 and 6 selective Chinook fisheries, 2003-2007.

## Total Encounters and Size/Mark-status Composition

Most of the Chinook caught in Area 5 were below the 22 -inch minimum size (sublegal-size) in 2003, but most were larger than 22 inches in 2004 through 2007 (Figure 14). Fish caught in Area 6 were almost exclusively larger than 22 inches (Figure 15). The proportion of Chinook that were marked was higher in Area 5 than in Area 6 (Figure 16). Mark rates in Area 5 appeared to increase during the 5 years of the fishery, but no trend is apparent in Area 6. The proportion of Chinook in four mark-status/size categories differed markedly between areas (Figure 17). For both areas, the proportion of Chinook that were legal-size and marked increased over the course of the study, while the proportion of sublegal-size unmarked fish declined (Figure 17 and Table 14).

## Test Fishery Size Analysis

Mean lengths (marked and unmarked combined) of Chinook encountered by test boats were significantly different between Area 5 and Area 6 for all five years of the study (Table 15). Mean lengths of Chinook caught in Area 6 were always larger than mean lengths of Chinook caught in Area 5.

Table 15. Mean length and statistical comparison of Chinook caught by test boats during the Areas 5 and 6 selective Chinook fisheries, 2003 through 2007.

## Voluntary Trip Reports

The number of Chinook reported on Voluntary Trip Reports varied dramatically over the 5 years of the fishery (Table 16). Whereas 213 angler trips were recorded in 2003, only 37 were recorded in 2006. Low sample sizes were recorded in Area 5 in 2004 and 2006, and in Area 6 in 2005 through 2007. In 2007, 80 of the 116 Chinook reported on VTRs, or $69 \%$, were from a single boat. Seventy-three of those 80 Chinook, representing $63 \%$ of the total VTR catch, were caught during a 6 -day period in late July.

Because anglers were discouraged from handling fish that were to be released and were not allowed to bring wild fish into their boat, there was potential for measurement error and misclassification of fish as marked or unmarked. Nonetheless, the mark rate for legal-size fish ranged from 20 to $74 \%$ (Table 17). Similar to test boats, VTRs suggested that the proportion of marked legal-size Chinook was higher in Area 6 versus Area 5, and that very few sublegal-size fish were present in Area 6 (Table 18). Sublegal-size Chinook never comprised more than 20\% of the encounters in Area 6. The number of marked legal-size Chinook released by anglers and recorded on VTRs ranged from 0 to $14 \%$, with a mean for all years and both areas of 5\% (Table 19). The highest release rate occurred in Area 5 during 2003 when 5 legal-size marked fish were released. Of the five reported releases, four of those were by a single WDFW biologist, which may bias the release rate high.

a. Four of the five fish were released by a single WDFW employee.

## Encounters and Total Mortalities

Despite concerns about angler's ability to accurately measure fish and determine the mark status, due to low samples sizes from the test boat in Area 6, we utilized a combined data set (test boat and VTRs) to determine the proportions of Chinook in each of the four mark status/size categories in both 2005 and 2006 (Table 20).

Annual encounter estimates for both areas combined ranged from 8,558 to 18,662 using Method 1 and from 6,362 to 13,476 using Method 2 (Table 21 and Appendix H). Note that the 8,558 estimated encounters in 2005 using Method 1 is slightly higher than reported in Table 12. This slight increase is because negative release numbers were set to zero. For years of low encounters, the difference between methods was as low as 2,196 fish (2005) while in the years with the higher encounters, the difference was as high as 6,447 fish (2004). Annual encounter estimates for both areas combined were always higher using Method 1 versus Method 2 (Table 21 and Appendix H). All of the Area 5 total encounter estimates were higher using Method 1, while in Area 6, the Method 1 estimates were higher in 2003, 2004, and 2007, but were slightly lower in 2005 and 2006. For Areas 5 and 6 combined, total encounter estimates for each of the four mark status/size categories were always higher using Method 1 versus Method 2 (Table 22). However, for separate areas, three of thirty Method 1 estimates were lower than Method 2 (by default, Method 2 estimates of legal-size marked are set at 0 ; Appendix H). The number of unmarked encounters generally declined each year of the fishery, except that all encounters were very low in 2005 (Table 22).

Annual mortality estimates, including both harvest and release mortalities, for both areas combined ranged from 3,221 to 6,193 using Method 1 and from 2,839 to 5,228 using Method 2 (Table 23). For years of low encounters, the difference between methods was as low as 382 fish (2005) while in the years with the higher encounters, the difference was as high as 1,069 fish (2004). Annual mortality estimates for both areas combined were always higher using Method 1 versus Method 2 (Table 24 and Appendix H). The number of unmarked mortalities generally declined each year of the fishery, except that all mortalities were very low in 2005 (Table 24). Whichever method is used to estimate mortalities, the ratio of unmarked mortalities to harvested marked legal-size Chinook has dropped steadily from 2003 through 2007 (Figure 18). The ratio ranged from 0.50 to 0.68 in 2003 and from 0.20 to 0.27 in 2007.

Table 20. Combined VTR and test fishing data set used to determine proportions of Chinook in four mark status/size categories in Area 6 during 2005 and 2006.

| Year | Method | Legal-size <br> Marked | Legal-size <br> Unmarked | Sublegal-size <br> Marked | Sublegal-size <br> Unmarked |

Figure 18. Ratio of unmarked Chinook mortalities per harvested marked legal-size Chinook in the Areas 5 and 6 selective Chinook fisheries, 2003 through 2007. Unmarked mortalities include release mortalities and illegal retention mortalities.

## CWT analysis

Over 540 coded wire tags (CWTs) were collected during the Areas 5 and 6 selective Chinook fisheries from 2003 through 2007 (Table 25 and Appendix I). Puget Sound stocks contributed the highest proportion of CWTs in each of the five years (Figure 19), followed by Columbia River stocks. Only five of the recovered CWTs were from stocks originating from rivers on the Washington side of the Strait of Juan de Fuca. The number of Double Index CWT recoveries ranged from 33 to 41 (Table 26 and Appendix J). The estimated number of mortalities that resulted from having this selective fishery versus a non-selective fishery ranged from 11 to 16 (Table 27 and Appendix K).

## Enforcement

The number of contacts made by enforcement officers ranged from 439 to 846 annually (Table 28). Of those contacts, the proportion cited or warned for sublegal-size Chinook was less than 0.01 for all areas and years. The proportion of contacts cited or warned for unmarked Chinook ranged from 0.00 to 0.03 .

## SECTION I: SUMMARY AND DISCUSSION

## Catch and Effort

Since the first few weeks of 2003, the overall Areas 5 and 6 selective Chinook fisheries were clearly driven by catch rate. During years that fishing was good, angler trips were up; during years that fishing was poor, angler trips were down. Surprisingly, the Chinook catch rate does not appear to be the main factor, but rather it appears that the overall salmon catch rate is the main factor responsible for how many angler trips are expended each season. Although we only briefly mention other species in this report, catch per angler of coho was substantially lower in 2005 through 2007 than in 2003 and 2004. The importance of the selective Chinook fishery is very evident in 2006, a non-pink year. Even though angler trips and angler trips/day were low in 2006, we believe effort would have been almost non-existent that year without a sustained Chinook fishery. Clearly, the selective Chinook fishery will have a greater effect on angler trips during even, non-pink years, than it will during odd, pink years. Effort levels in 2007 were surprisingly low given the good catch rates of both Chinook and pink salmon. We speculate that higher fuel prices may be affecting angler's willingness to travel to destination fishing locations such as Sekiu. Fuel prices will likely be a factor in future effort levels at Sekiu.

After seven years of summer-time Chinook closures, non-selective Chinook quota fisheries were implemented in Area 5 during 2001 and 2002 to harvest a small number of these fish. These fisheries utilized the quota in 10 days during 2001 and in 5 days during 2002. We examined the difference in effort occurring in Area 5 during these non-selective quota years versus effort during the selective fisheries years (Tables 29 through 34). For 2003 through 2005, the selective fisheries effort was higher than either 2001 or 2002 during comparable seasons. For 2006 and 2007, the selective fisheries effort in Area 5 was lower than the effort in 2001 and was higher than the effort in 2002. Tremendous coho catches were observed in Area 5 during 2001 and effort was likely bolstered by good coho fishing during that year.

We also examined effort levels estimated from Catch Record Cards from 1984 through 2006 for each area. Effort in Area 5 clearly shows an increase over the 1994 through 2000 period, when no Chinook retention was allowed and coho fishing was closed in certain years (Figure 20). However, the effort level was considerably below the levels observed from 1984 through 1993 even though the number of days open approached the historical level. Surprisingly, effort in Area 6 does not show an increase compared to the 1994 through 2000 period (Figure 21). Similar to Area 5, the Chinook selective fisheries effort is considerably below the levels observed from 1984 through 1993. These data suggest that the combination of both selective coho and selective Chinook fishing will result in effort levels lower than historical. Despite the lower effort levels observed in Area 5 during 2006 and 2007 relative to 2001, results of this study suggest that given the low catch rate of coho in 2003 through 2007, the addition of the selective Chinook fishery increased effort (angler trips) in each year of the fishery relative to what effort would have been without the selective Chinook fishery.

Prior to implementation of the 2003 selective Chinook fishery, fisheries managers and anglers were unsure about what level of angler effort would be expended in a marine selective Chinook
fishery and how long the quota would last. Historically, Area 5 was one of the highest effort areas in Puget Sound. For example from 1984 through 1993, anglers made an average of nearly 50,000 angler trips per month during July, August, and September. When the 2003 fishery was announced, it created substantial excitement among the recreational fishing community, with many anglers believing that fishing would be similar to the "good old days". As we observed, effort during the initial weeks of the 2003 fishery was relatively high given the catch rate. However, for many folks the reality soon set in that selective Chinook fisheries were not the "good old days". During the first year of the fishery, some anglers were disappointed when they were unable to catch any marked Chinook to retain and had to release a number of unmarked Chinook. It took a season for some anglers to understand that harvest opportunities were lower in selective fisheries than in non-selective fisheries. But it also became apparent that the quota was going to last much longer than the 10 and 5 day 2,000 fish non-selective Chinook fisheries in 2001 and 2002. Anglers did not need to rush out and fish in the first week of the fishery to ensure an opportunity to participate as they did during the 2001 and 2002 non-selective fisheries. As such, the initial rush of anglers declined quite rapidly after the first few weeks of 2003 and effort appears to have stabilized between 20,000 and 30,000 angler trips per year during this fishery. Based on our results, opening of a selective Chinook fishery does not necessarily lead to effort levels that are near or substantially higher than historical levels and in fact, in the Area 5 and 6 selective Chinook fisheries, effort was well below historical levels.

Figure 20. Comparison of days open for Chinook retention and angler effort (trips) measured by baseline sampling and Catch Record Cards in Marine Area 5, 1984 through 2006. Data after March 2002 are still preliminary.

Figure 21. Comparison of days open for Chinook retention and angler effort (trips) measured by baseline sampling and Catch Record Cards in Marine Area 6, 1984 through 2006. Data after March 2002 are still preliminary.

Table 29. Estimated effort and harvest in the 2001 and 2002 non-selective Chinook fisheries in Area 5 compared to the 2003 Area 5 Chinook Mark-Selective Fishery, July 5 through August 3, 2003.

| Year | Quota | Days Open for Chinook | Date of Comparison | Chinook Daily Limit $(\geq 22$ ") | Angler Trips | Chinook Harvested $^{\text {a }}$ |

Final Working Draft 3-14-08

Table 33. Estimated effort and harvest in the 2001 and 2002 non-selective Chinook fisheries in Area 5 compared to the 2007 Area 5 Chinook Mark-Selective Fishery, July 1 through August 4 and August 9, 2007.

| Year | Quota | Days Open for Chinook | Date of Comparison | Chinook Daily Limit ( $\geq 22$ ") | Angler Trips | Chinook Harvested $^{\text {a }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2001 | 2,000 | 10 |  <br> August 9 | Any 1 | 22,738 | 1,800 |
| 2002 | 2,000 | 5 |  <br> August 9 | Any 1 | 11,194 | 1,782 |
| 2007 | $4,000^{\mathrm{b}}$ | 36 |  |  |  |  |
| August 9 |  |  |  |  |  |  |

a. Does not include any illegal harvest during days that Chinook retention was not allowed.
b. The quota applied to Area 5 and the western portion of Area 6.

Another concern of fishery managers and anglers prior to implementation of this fishery was the mark rate that would be observed on Chinook. When mark rates during selective coho fisheries fall below about $33 \%$, numerous emails, telephone calls and letters are received by WDFW voicing concern about the fisheries. The mark rate on legal-size Chinook has been very good in this fishery and has been on an increasing trend over time. Anglers have been able to retain about 1 out of every 2 legal-size Chinook they have caught. Although we have not collected data on angler issues directed to WDFW, as opposed to selective coho fisheries during years of low mark rates, very few concerns have been raised about the mark rate on Chinook in this fishery. Virtually all concerns identified by anglers and received by WDFW regarding the Areas 5 and 6 selective Chinook fisheries are questions about the method of estimating harvest and disbelief that the quota has been reached. As the proportion of hatchery Chinook that are marked continues to increase in Puget Sound, the mark rate observed in this fishery should also continue to increase.

The number of Chinook harvested per day in this fishery has ranged from approximately 50 to 115 per day. For future fisheries planning, assuming 100 Chinook harvested per day would be a good conservative estimate. Assuming 100 fish harvested per day for a thirty day fishery would equate to 3,000 Chinook. For comparison, if the actual number harvested was 116 per day (the highest value observed), the harvest would be 3,480 or $16 \%$ over the predicted value.

## Test Boats and VTRs

Given that the two Areas are adjacent to each other, the difference in the size composition of Chinook available to anglers is remarkable. Whichever method is used to evaluate encounters, creel surveys, VTRs, or test fishing, it is abundantly clear that the Area 5 fishery has a higher proportion of sublegal-size Chinook than Area 6. Sublegal-size Chinook have been almost nonexistent in Area 6 during the five years this fishery has occurred.

## CWT Analyses

Based on CWT recoveries, the Area 5 and 6 selective Chinook fishery is impacting mostly Puget Sound and Columbia River stocks. Recoveries of Strait of Juan de Fuca stocks have been surprising low. While a complete cohort based CWT analysis has not yet been completed, based on our estimates of marked and unmarked DIT tagged Chinook, the overall bias introduced to the CWT program due to this fishery is extremely low. Hagen-Breaux (2007) analyzed lambda at release versus lambda at recovery for Puget Sound DIT Chinook stocks and determined that there was no detectable difference due to selective Chinook fisheries conducted to date.

Although not intended to capture the complete impacts of these selective fisheries on local stocks, we examined the number of recovered CWTs from 1999 through 2002 brood year Chinook originating from the Washington State side of the Strait of Juan de Fuca as reported in the Regional Mark Information System (RMIS) in order to gain a relative measure of the effects of these fisheries. From 2001 through 2006, 1,027 Strait of Juan de Fuca CWTs were recovered
in fisheries, broodstock collection, or on the spawning grounds (Table 34). Only seven were recovered from recreational fisheries in Washington State, including the three recovered during the Areas 5 and 6 selective Chinook fisheries. These tags represent less than 1 percent of all recoveries (Table 35). Nearly 29 percent of the recoveries occurred in fisheries in Canada and Alaska.

Table 34. Recoveries of Washington State Strait of Juan de Fuca origin coded wire tags (CWTs) from 1999 through 2002 brood year Chinook salmon in fisheries or escapement from 2001 through 2006 as reported in RMIS.

## Enforcement Compliance Compared to Creel Compliance

Our enforcement reports are not intended to be an unbiased estimate of angler compliance. However, they are a relative index of compliance that can be contrasted with creel survey results. For most areas and years, the estimated encounters from the creel survey (Appendix G) noted a higher proportion of either unmarked or sublegal-size Chinook than the enforcement encounters (Table 36). Both creel survey and enforcement data suggest a very high rate of compliance, with overall compliance for both areas combined at $90 \%$ or better for each of the five years.

Table 36. Comparison of enforcement percent of contacts that had sublegal-size Chinook or unmarked Chinook and percent of each from estimated landed catch (see Appendix G) during the Area 5 and 6 selective Chinook fisheries, 2003 through 2007.

## SECTION II: ASSESSMENT OF THE SELECTIVE FISHERY SAMPLING PROGRAM AND ANALYSIS METHODS

## Sampling intensity-related questions:

The Puget Sound Sampling Program Operational Plan lists the following objective for the Areas 5 and 6 (and Elliott Bay) fisheries with in-season catch estimates:

- Sampling size will be established based on previously tested designs for Terminal Area Fisheries and will be sufficient to provide total estimates of harvest and effort to be within $15 \%$ of the point estimate at a $95 \%$ confidence level.

The Plan further lists the following objectives for Selective Fisheries:

- For creel sampling, sample size is set at 100 encounters (observed retained plus reported released fish) per area and week for coho and per area and month for Chinook.
- At least $10 \%$ of the fishery will be sampled for coded wire tags (CWTs) with a goal of $20 \%$ for any Chinook selective fisheries.
- For the test fishery, the sampling goal is set at a minimum of 100 salmon encounters per stratum (management regime).

Harvest estimate precision ranged from 0.1295 to 0.1930 during the five years of the fisheries and met the 0.15 precision objective four out of the five years (Table 37). The only year that the objective was not met was during 2005, when fishing was very poor and the quota was not achieved. Effort estimate precision ranged from 0.0660 to 0.1546 during the five years of the fisheries and therefore met the 0.15 precision objective each year (Table 37).

Baseline sample-size objectives were met for most statistical months and areas (Table 39). The objective was not met in Area 6 during August in 2005, 2006 and 2007. Not meeting the objectives in 2005 and 2006 was primarily due to low effort and the fishery being open for only part of the month ( 10 days in 2005 and 19 days in 2006), and in 2007 due to the fishery only being open for one day in statistical month August. Sample size objectives likely would have been met if the fisheries were open for the entire statistical month of August.

Weekly sample rates ( $n$ fish examined / estimated harvest) ranged from 0.154 to 0.544 in Area 5 (Table 40) and from 0.162 to 0.777 in Area 6 (Table 41). Overall fishery sample rates ranged from 0.227 to 0.276 in Area 5 and from 0.326 to 0.558 in Area 6. The overall fishery sample rate objective (for CWT recoveries) of $20 \%$ was met each year in each area.

Test fishery encounters ranged from 80 to 335 in Area 5 and from 10 to 148 in Area 6 (Table 42). The test fishery encounter objective was met in Area 5 each year except in 2007, while in Area 6 the objective was not met in 3 of the 5 years.

## Comparing Private Fleet, TF, and VTR data

A key assumption of both methods of calculating mortalities is that the test-fishery and privatefleet encounter composition (i.e., frequency by mark-status/size categories) is identical (Assumption 6, Appendix C). To evaluate this assumption, we compared mark rates, size, and proportions of fish caught by the fleet as a whole through creel surveys, fish caught and reported on VTRs by anglers, and fish caught by test fishing.

In Area 5, test boats caught more Chinook than anglers recording their catch on VTRs in all years except 2007 (Table 43). In Area 6, anglers reporting their catch on VTRs caught more Chinook than the test boats did in 2005 and 2006. During years of poor fishing (2005 and 2006), very low samples sizes were reported for both VTRs and test boats.

## Size

Due to concerns about the accuracy of the measurements in the VTR data, we did not compare lengths of Chinook from VTRs with creel survey or test boat data. Although test boat sample sizes in Area 6 were low in 2005 and 2006, length frequency distributions suggest that mean length and length distributions were similar between test fishing and angler caught Chinook measured during creel surveys for each Area (Figures 22 and 23). The length frequency distributions are remarkable in the similarity of the size distributions in each individual area for each year, and in their differences between the Areas. Mean length and distribution of lengths were not statistically compared for Area 6 in 2006 because of small sample sizes. Mean lengths and distribution of lengths were not significantly different between test fishing and creel surveys for all comparisons made, except for Area 5 in 2007 (Table 44). Thus both test fishing and creel surveys clearly demonstrate the similarities within sections annually and demonstrate the difference in size distribution of Chinook between Area 5 and Area 6.

## Mark Rate

Overall mark rate varied between the three methods in both areas, but also showed differences between areas (Figure 24). Mark rate was more variable between methods in Area 5 than in Area 6. In Area 5, mark rates reported by anglers during creel surveys were always the lowest rate of the three methods. The highest mark rate was reported for VTRs in 3 of the 5 years. In Area 6, VTRs always had an intermediate mark rate between test boats and creel surveys. The highest mark rate was reported by test boats for 3 of the 5 years. For legal-size fish in Area 5, mark rate was between 43 and 57\% for test boats and between 20 and $74 \%$ for VTRs (Figure 25). For legal-size fish in Area 6, mark rate was between 40 and $67 \%$ for test boats and between 30 and $100 \%$ for VTRs (Figure 25). Legal-size mark rate in Area 6 was relatively similar between test fishing and VTRs for all years except 2005.

We tested for differences in overall mark rates (i.e., total marked encounters / total encounters) between test-fishery, VTR, and dockside sampling methods and legal-size mark rates (i.e., legalmarked encounters / total legal encounters) between test-fishery VTR observations using $\chi^{2}$ proportion tests (with Yates continuity correction). For Area 5 overall mark rate, highly
significant differences in mark rates were noted for all five years except 2006 (Table 45). In 2003 and 2007, the creel survey and VTR comparison and the test fishery and creel survey comparisons were significantly different, while the test fishery and VTR comparison was not significantly different. In 2004 and 2005, the test fishery and VTR comparison and the test fishery and creel survey comparisons were significantly different, while the creel survey and VTR comparison was not significantly different. For Area 6, a significant difference in overall mark rates was observed only for 2004. In that year, the entire difference was due to a highly significant difference between the test fishery and creel survey. Although the difference in legalsize marked rate was quite large in some years (Table 46), a significant difference was observed only for Area 5 in 2005, with 2004 in Area 5 also close to being significantly different ( $\rho=$ 0.082).

Table 43. Number of Chinook caught by test boats and recorded by anglers on Voluntary Trip Reports (VTRs) in the Areas 5 and 6 selective Chinook fisheries, 2003 through 2007.

Figure 25. Proportions that were marked, and $95 \%$ confidence intervals, of legal-size Chinook caught by test fishing boats and reported caught by anglers on Voluntary Trip Reports (VTR) during the Area 5 and 6 selective Chinook fishery, 2003 through 2007.

## Size and mark status categories

Creel data were not collected with enough detail on mark and size status of released salmon to compare with test fishing and VTRs for proportions of Chinook in each of the four size and mark status categories. Proportions in each the mark-status/size categories were not significantly different in most comparisons (Figure 26 and Table 47). Significant differences were observed in Area 5 in 2006 and 2007 and in Area 6 in 2007 (Table 47). The 2007 Area 5 differences might be a result of a biased VTR sample as most of the VTR data was collected from 1 boat during a 6 -day period. The proportion of legal-size marked Chinook in Area 5 was always lower for VTR data than test boat data, except in 2003 when they were essentially equal. In Area 6, test fishing and VTR data showed very similar proportions of the four mark status/size categories for each year except 2007 when anglers reported more sublegal-size fish than the test boats. The proportion of legal-size marked Chinook in Area 6 was always lower for VTR data than test boat data, except in 2006.

In Area 5, confidence intervals around proportion estimates were almost always smaller for test fishing estimates versus VTR estimates (Figures 27 and 28). In Area 6, confidence intervals were smaller for test fishing in 2003, 2004 and 2007, but were larger in 2004 and 2005 when sample sizes were extremely low (Figures 29 and 30).

## Estimation of Total Encounters, Method 1 versus Method 2

In previous post-season selective fishery reports (e.g., WDFW 2007b, 2007c) and in Section I of the present document, WDFW has noted that Method-1 (M1) and Method-2 (M2) estimates of total Chinook encounters (and quantities that are estimated from total encounters; see Appendix A for details) sometimes differ substantially. In particular, M1 estimates of Chinook releases (and associated mortality) have been on average $50 \%$ higher (range: $11 \%$ lower to $238 \%$ higher) than M2 estimates over the suite of selective seasons monitored to date (i.e., 2003-2007 in Areas 5 and 6, 2004-5 and 2006-7 in 8-1 and 8-2, and 2007 in Areas 9, 10, and 11; Figure 31). While M2 was originally added to the creel estimation process with sound justification (i.e., because angler-reported releases were perceived as inaccurate at times), the simultaneous reporting of two estimates introduces ambiguity to the fishery-evaluation process. In particular, it can be difficult to draw precise, quantitative post-season conclusions about the success of fisheries relative to pre-season objectives (e.g., FRAM-predicted vs. observed impact comparisons, Section II) when multiple impact estimates are available for consideration.

Figure 31. (A) (left) Season-wide Method-1 (M1) vs. Method-2 (M2) encounter rates (total encounters / total angler trips) for all Puget Sound/Strait of Juan de Fuca selective fisheries monitored using the Murthy design, 2003-2007. The dashed line reflects a $1: 1$ relationship; the solid line is the fitted relationship. (B) (right) The ratio of M1 to M2 total encounter estimates ("Exaggeration Ratio") as a function of M2 encounter rates for all selective fisheries monitored using the Murthy design with test fishing, 2003-2007. The dashed horizontal line represents the line of estimator equality whereas the solid horizontal line reflects the overall mean for fisheries and seasons considered.

For these reasons and with the encouragement of tribal technical staff, we sought to resolve which estimation scheme (M1 and M2) is most appropriate for selective fishery evaluation. Our specific goal was to discern which approach is most likely to yield unbiased estimates of fishery impacts relative to actual (unknown) impacts. To do this, we evaluated: i) M1 and M2 estimators and their associated assumptions, $i$ i) the sensitivity of estimators to assumption violations, and iii) the validity assumptions based on indirect evaluations using empirical data. Based on these efforts, we propose and recommend alternatives for data collection and parameter estimation in selective Chinook fisheries monitored using our standard Murthy design.

## Method 1 and Method 2 Estimators: Assumptions and Sensitivity Analysis

Though M1 and M2 estimators (and their variances) are detailed in Section I and Appendix A, we review them briefly here to set the stage for the present evaluation. M1 and M2 rely on the same information for the harvested Chinook component (dockside-based Murthy total estimates) but differ computationally and in terms of the data inputs needed for released Chinook (and therefore total encounters) estimation. M1 Chinook encounters ( $E_{\mathrm{TOT}}$ ) are obtained by summing dockside-based total estimates ( $N$ ) of retained and released Chinook encounters for six estimation categories [subscripts: marked-kept (MK), unmarked-kept (UK), marked-released (MR), unmarked-released (UR), unknown mark status-released (unkR), and apportioned unidentified salmon (AUS)]:

$$
\begin{equation*}
E_{\mathrm{TOT}}=N_{\mathrm{MK}}+N_{\mathrm{UK}}+N_{\mathrm{MR}}+N_{\mathrm{UR}}+N_{\mathrm{unkR}}+N_{\mathrm{AUS}} \tag{1}
\end{equation*}
$$

Given its reliance on creel data, the validity of M1 release estimates (relative to M2) hinges on the ability and/or willingness of anglers to accurately recall and/or report released Chinook encounters during the interview process (i.e., Assumption 3 from Section I; Appendix B).

Accepting the potential for Assumption-3 violation, M2 approaches encounters estimation by combining sampler observations on landed fish only (i.e., Murthy estimates for legal-marked Chinook in particular), assumptions about angler behavior (i.e., they harvest all legal-marked Chinook encountered), and auxiliary information (collected via test fishing) about the size/markstatus composition of the at-large "fishable" (i.e., vulnerable to encounter with hook-and-line angling gear) Chinook population. Using a simple Peterson estimator, M2 encounters are estimated as:

$$
\begin{equation*}
E_{\mathrm{TOT}}=K_{\mathrm{LM}} / p_{\mathrm{LM}} \tag{2}
\end{equation*}
$$

where $K_{\mathrm{LM}}$ is the dockside estimate of legal-marked Chinook retention (apportioned Murthy estimate based on size composition of dockside samples) and $p_{\mathrm{LM}}$ is the proportion of test-fishery encounters that were legal-sized and marked. Thus, the accuracy of M2 estimates is unaffected by the reliability of angler-reported releases and instead depends on whether or not anglers report all legal-marked Chinook encountered (Assumption 5, Appendix B) and the extent to which the size/mark-status composition of test-fishery encounters mirrors that seen by private anglers (Assumption 6, Appendix B).

To understand which estimator (M1 or M2) is most appropriate for estimating total encounters in selective Chinook fisheries with accuracy, the plausibility of Assumptions 3, 5, and 6 and the sensitivity of estimators to departures from their perfect attainment must be considered. While the latter portion of this section addresses the validity of Assumptions 3, 5, and 6, we briefly evaluate the effects of hypothetical assumption violations on the accuracy of estimates here.

We evaluated bias in total encounter estimates ( $E_{\mathrm{TOT} \text {-est }}$ ) generated by M1 and M2 estimators under known harvest, release, and size/mark-status ( $p_{\mathrm{LM}}$ in particular) conditions given a range of proportional departures from perfect assumption attainment for each one ( 3,5 , and 6 ) independently. We considered an "average" case where 3,500 Chinook were encountered in total ( $E_{\text {TOT-true }}$ ) of which $10 \%$ were legal in size and marked ( $p_{\text {LM-true }}$ ) and thus available for harvest (i.e., $E_{\mathrm{LM}}$-true $=350$; this analysis assumes only LM Chinook are harvested). The sensitivity [assessed in terms of relative bias, i.e., Relative Bias $=\left(E_{\text {TOT-est }}-E_{\text {Tot-true }}\right) / E_{\text {Tot-rue }}$ ] of the M1 estimator to departures from Assumption 3 (i.e., accurate release reporting occurs) was assessed using the encounters estimates:

$$
\begin{aligned}
& E_{\mathrm{TOT}-\text { est }}=N_{\mathrm{K}}+N_{\mathrm{R}} * D, \text { and } \\
& \qquad E_{\mathrm{TOT}-\text { true }}=N_{\mathrm{K}}+N_{\mathrm{R}},
\end{aligned}
$$

where $N_{\mathrm{R}}{ }^{*} D$ is the release value observed through sampling and $D$ is the modeled departure between reality and assumptions (i.e., the misreporting rate for released fish in the case of Assumption 3); $D$ was assessed from 0.05 to 1.95 [i.e., $+/-95 \%$ deviations from Assumption 3 being perfectly met $(D=1)]$. $N_{\mathrm{K}}$ was assumed to be 350 (all legal-marked fish were harvested) and $N_{\mathrm{R}}$ - the number of fish released - was taken as the remainder (3,150 fish).

The sensitivity (~Relative Bias) of M2 estimates to Assumptions 5 (all legal-marked Chinook are retained) and 6 (test fishery and fleet encounters are the same) departures was similarly quantified. However, for assumption $5, E_{\text {TOT-est }}$ and $E_{\text {TOT-true }}$ were estimated as:

$$
\begin{align*}
E_{\mathrm{TOT}-\text { est }} & =\left[E_{\mathrm{LM}-\text { true }} *(1-D)\right] / p_{\mathrm{LM}-\text { true }}  \tag{4}\\
& E_{\mathrm{TOT}-\text { true }}=E_{\mathrm{LM}-\text { true }} / p_{\mathrm{LM} \text {-true }}
\end{align*}
$$

where the quantity $E_{\mathrm{LM}-\text { true }} *(1-D)$ is what is observed through dockside sampling and $D$ represents the legal-marked release rate, which was evaluated for a range of 0-0.95 (i.e., it is bound to the range 0 and 1). For Assumption-6 sensitivity, $E_{\text {TOT-est }}$ and $E_{\text {TOT-act }}$ were estimated as:

$$
\begin{align*}
& E_{\text {TOT-est }}=E_{\mathrm{LM} \text {-true }} /\left(p_{\mathrm{LM} \text {-true }} * D\right)  \tag{5}\\
& E_{\text {TOT-true }}=E_{\mathrm{LM}-\text { true }} / p_{\mathrm{LM} \text {-true }},
\end{align*}
$$

where $p_{\text {LM-true }}{ }^{*} D$ yields the value that is observed in test fishery samples and $D$ is the degree of departure between test fishery legal-marked and actual fleet legal-marked encounters ( $D$ values from 0.05 to 1.95 were assessed).

Based on this cursory sensitivity analysis, four issues about the effects of assumption violations on the reliability of M1 and M2 estimates became apparent. First, for Assumptions 3 and 5, discrepancies of similar magnitude affect the accuracy of estimates to a similar extent (on an $\sim 1: 1$ basis; Figure 32). Incremental under- and over-reporting of actual releases (i.e., Assumption 3) leads to proportional negative and positive biases in M1 estimates; the relative bias in M2 estimates varies inversely and proportionally with the rate at which legal-marked Chinook encounters are released by anglers (i.e., Assumption 5). Second, M2 bias varies nonlinearly (via a hyperbolic function) with the degree of departure between test-fishery and fleet legal-marked encounters; thus, estimates are more (and positively) biased if test fishers have fewer legal-marked encounters than the private fleet than if the opposite scenario is true [e.g., a $20 \%$ discrepancy towards test-fishers having fewer legal-marked encounters leads to a $25 \%$ relative bias (overestimate) in encounters whereas the opposite (i.e., test fishers having more legal-marked encounters) yields only a $17 \%$ bias (underestimate)]. Third, although we did not evaluate estimator sensitivity to simultaneous assumption violations, it is clear that M2 could yield accurate estimates of total encounters if both Assumption 5 and 6 are not well met. For example, compensation might occur if anglers released legal-marked Chinook encounters (leading to negative bias) and fewer legal-marked Chinook were caught by test fishing than private-fleet anglers (leading to positive bias). Finally, while estimators were equally sensitive to the three different assumption violations on average, departures in Assumption 6 (test-fishery assumption) yielded the maximum level of bias across all levels considered.

Figure 32. Relationship between relative bias in total encounter estimates [i.e., (estimate actual) / actual] and assumption violations of proportionally varying degrees (D) for Assumptions 3 (anglers accurately report all released fish), 5 (anglers keep all legal-marked Chinook encountered), and 6 (the test fishery and fleet encounter Chinook in the same size/markstatus composition).

## Evaluating the Validity of Estimator Assumptions

Assumption 3: Do anglers accurately report caught-and-released Chinook salmon?
To gauge the plausibility of Assumption 3, we conducted a brief literature review, considered patterns in empirical estimates, and inspected raw interview data (i.e., release-frequency distributions). From this, we concluded that Assumption 3 is unlikely to be perfectly met and that in general anglers probably over-report released encounters. While the rate at which anglers over-report released encounters is unknown, original 8-1/8-2 data and previous studies suggest that it could be anywhere between $20-200 \%$.

In Washington (Noviello 1998) and elsewhere (e.g., NRC 2006; Bailey 2007), interview-based catch information (inclusive of harvested and released components) is generally accepted as being vulnerable to several forms of response error. Whether due to innate human tendencies towards recalling/reporting catch in prototype quantities (i.e., digit bias, where even numbered and multiples-of-five responses are favored; e.g., Beaman et al. 2005), intentional over-reporting of catch for status purposes (i.e., prestige bias), or other reasons, the misreporting of encounters occurs often and can significantly bias interview-based estimates of catch (Malvestuto 1996; Pollock et al. 1994). For example, in a comparison of angler-based and "true" total catch estimates for Alberta walleye fisheries, Sullivan (2003) found that anglers reported sublegal releases at a rate 2.2 times the release level which actually occurred. Applying Sullivan's methodology (i.e., he based "true" encounters on an M2-like estimator, i.e., with landed catch expanded by test-fishery proportions) to Washington's selective fisheries suggests an overreporting rate of similar magnitude (i.e., M1 is 1.5 times M2 on average; e.g. Figure 32).

Specific to marine recreational salmon fisheries, Noviello (1998) demonstrated that anglers do over-report the released component of their catch in some fisheries. In this study, the overall (i.e., across 7 season-area strata) angler-reported release proportion was $+18 \%$ [range: $-19 \%$ (Area 4 pink salmon) to $+353 \%$ (Area 10 all salmon)] biased compared to the actual value documented via on-the-water observation methods. By inspecting release-frequency distributions, Noviello (1998) also showed that anglers tend to report releases in prototype quantities (e.g., $10,12,15,20$ ) and therefore suggested a role of digit bias in the over-reporting process. Similar reporting tendencies were reported by WDFW (2008) in the Areas 8-1 and 8-2 selective winter blackmouth fisheries; evidence suggesting digit bias was especially pronounced for high-encounter periods (e.g., October in the 06-07 season; Figure 33). Although digit bias is likely the result of complex cognitive processes that are beyond the scope of selective fisheries monitoring, its presence can be an impediment to the accurate estimation of population parameters from interview data (Huttenlocher et al. 1990; Beaman et al. 2005).

In combination, these observations lead us to speculate that: $i$ ) anglers misreport actual releases by recalling/reporting in prototypical bins, ii) misreporting likely involves erring towards overestimation, and iii) Assumption 3 is poorly met in some cases (e.g., during periods of high encounters).

Figure 33. Histograms of reported salmon releases (all species) from pooled Areas 5 \& 6 interviews, 2003-07. The plotted frequency is the proportion of anglers interviewed that successfully encountered and released Chinook salmon. In sequential order (2003-2007), the season-total samples size (no. parties interviewed) represented by each plot are $n=858,1,392$, 751,827 , and 730 and $n=1,917$, respectively.

Assumption 5: Do anglers keep all of the legal-marked Chinook they encounter?
Though the data needed to rigorously evaluate Assumption 5 are limited, available information suggests that it is likely violated but only to a minor extent. To arrive at this conclusion, we considered all available direct [empirical estimates of legal-marked release rates from voluntary trip reports, VTRs] and indirect evidence relating to its occurrence.

The availability of empirical data for evaluating the plausibility of Assumption 5 is limited for multiple reasons. Foremost, to discourage the over-handling of fish in protected size/mark-status classes (marked or unmarked), WDFW has historically avoided asking anglers about the size of released individuals; thus, legal-marked release rate estimates cannot be obtained for the private recreational fleet. Second, even if interviews included questions about the release of legalmarked fish, however, an unknown (and non-estimable) proportion of the legal-marked Chinook release that occurs in a fishery could be due to misidentification (i.e., mark-status determination, length measurement, or both). Third, VTRs - our only direct means for estimating legal-marked release rates in a fishery - are the result of a self-selected sample coming from a more skilled segment of the angling population (see Section I for justification); legal-marked release rates estimated from VTRs are therefore potentially biased (and most likely in the positive direction).

Given appropriate caveats about the potential for bias in VTR-based samples, data collected and returned by private and charter anglers fishing in Areas 5 and 6 yield a legal-marked release rate estimate of approximately 0 to $14 \%$ (overall estimate, $5 \%$ ) for the combination of seasons and areas (Table 19). We found VTR estimates of legal-marked release rates to be similarly low and consistent for season-area-source combinations where sufficient legal-marked encounters were reported.

Overall, VTR observations and test-boat vs. fleet comparisons of legal-marked Chinook size suggest that Assumption 5 is unlikely to be met in the 5 and 6 fishery. However, VTRs provide a starting point for adjusting M2 estimates so that they may more accurately reflect reality (i.e., by expanding legal-marked Chinook retention by $\sim 10 \%$ prior to using this value in the M2 estimator). If a more defensible estimate of the private fleet legal-marked release rate could be obtained (e.g., based on reported intentional legal-marked release activity supplied during interview, Assumption-3 issues notwithstanding), this could also be used in modifying future estimates.

Assumption 6: Is the size/mark-status composition of test fishery encounters the same as that seen by the private recreational fleet?

In the previous subsection of the present report, we addressed this assumption in detail both in terms of how test fishing proceeds in implementation (i.e., do test-boat anglers perfectly mimic the fleet?) and based on comparisons of parameter estimates that could be obtained from both the test-boat and the private-fleet datasets (i.e., overall mark rates and size/age composition for legalmarked Chinook). Several lines of evidence suggest that this assumption is correct. We refer the reader to the previous subsection for more on our consideration of this assumption.

## FRAM Performance in Selective Fishery Planning

Predictions of encounters, landed catch and mortalities by FRAM were relatively accurate for the Area 5 and 6 selective Chinook fishery. In general, actual estimated encounters, landed catch and mortalities of marked fish were occasionally higher than FRAM predictions, and actual estimated encounters, landed catch and mortalities of unmarked fish were almost always less than FRAM predictions.

Estimates of actual landed catch exceeded FRAM predictions every year except 2005 for marked legal-size fish, and every year for marked sublegal-size fish (Table 48). Estimates of actual landed catch of unmarked legal-size fish never exceeded FRAM predictions, while in 2005, 2006 and 2007, estimated actual landed catch of unmarked sublegal-size fish exceeded the FRAM predictions of zero. Estimates of total unmarked landed catch were from less than 1 percent to 26 percent of the FRAM predictions.

Using Method 1 estimates of encounters, actual estimates exceed FRAM predictions every year except 2005 for marked legal-size fish, and for unmarked sublegal-size fish in 2003 (Table 49). However, even under this most conservative estimate (highest estimate) of encounters, estimated actual total encounters of unmarked Chinook were less than FRAM predictions for all five years of the fishery (Figure 34). Using Method 2 estimates of encounters, actual estimates exceed FRAM predictions in 2003, 2004 and 2006 for marked legal-size fish, and for unmarked sublegal-size fish in 2003 (Table 50). Using Method 2 estimates, total encounters of unmarked Chinook never exceeded the FRAM predictions.

Using Method 1 estimates of mortalities (including both kept and released fish), actual estimates exceed FRAM predictions every year except 2005 for marked legal-size fish and total marked fish, in 2004 for marked sublegal-size fish, and for unmarked sublegal-size fish in 2003 (Table 51). However, even under this most conservative estimate (highest estimate) of mortalities, the estimated actual total fishing mortality of unmarked Chinook was less than the FRAM prediction for all five years of the fishery (Figure 35). Using Method 2 estimates of mortalities, actual estimates exceed FRAM predictions in 2003, 2004 and 2006 for marked legalsize fish, and for unmarked sublegal-size fish in 2003 (Table 52). Using Method 2 estimates, total mortalities of unmarked Chinook never exceeded the FRAM predictions.

Figure 34. Comparison of FRAM predicted mortalities of marked Chinook (based on Method 1 and Method 2 estimates of encounters) and actual mortality estimates from the Areas 5 and 6 selective Chinook fisheries, 2003 through 2006.

Figure 35. Comparison of FRAM predicted mortalities of unmarked Chinook (based on Method 1 and Method 2 estimates of encounters) and actual mortality estimates from the Areas 5 and 6 selective Chinook fisheries, 2003 through 2006.

Unmarked retention error ranged from less than 1 percent to just under 2 percent (Table 53), well below the FRAM value of 8 percent. Using Method 1 estimates, marked release error ranged from 24 to 37 percent, many times greater than the FRAM value of 6 percent. Unmarked sublegal-size retention error and marked sublegal-size retention error are modeled as zero in FRAM. Unmarked sublegal-size retention error ranged from 0 to 8 percent, while marked sublegal-size retention error ranged from 6 to 19 percent. Marked sublegal-size retention error increased over the five years of the fisheries.

## SECTION II: SUMMARY AND DISCUSSION

## Sampling Intensity

These monitoring and sampling programs were designed to collect and provide data to estimate the following parameters, as listed in the State-Tribal agreement documents (Northwest Treaty Tribes and the Washington Department of Fish and Wildlife 2007). For the most part, the monitoring program used for the Area 5 and 6 selective Chinook fisheries from 2003 through 2007 has been very effective at achieving the goals and objectives as outlined in those agreements.

Our estimates of harvest were within the $15 \%$ precision objective during all years that the quota was achieved and effort estimates achieved the objective each year. Even in 2005 when the quota was not harvested, our precision was within $20 \%$. Although better precision is desirable for all years, the precision achieved in 2005 was such that even if we added the upper end of the confidence interval to the harvest estimate, we still did not exceed our conservation objectives. Sample size objectives were met when the fishery encompassed the entire statistical month. We still met our precision estimate in 2 of the 3 years when the August sample size objective was not met. Sampling rate for CWTs was met each year of the fishery. Based on the precision and sample rates achieved, we believe that the dockside-sampling program for summer selective Chinook fisheries with quotas should remain unchanged.

Test fishery encounters met objectives in Area 5 in all years except 2007. The number of hours expended test fishing was down in 2007 versus previous years. Future test fisheries must ensure the desired sample is reached. In Area 6, the test fishing objective was met only twice. The stated objective of 100 fish caught is probably unrealistic given the entire estimated encounters for Area 6 ranged from 683 to 1,614 during the years the objective was not met. An objective of 100 fish would represent between 6 and $14 \%$ of the angler encounters. An alternative test fishing objective for short duration, low catch rate fisheries should be investigated. Despite the deficiencies in test fishing sample size in Area 6, the test fishing data still matched well with creel data and clearly showed the difference in the size of fish being caught in Area 6 versus Area 5.

## Evaluation of Mark Rates and Mark Status/Size Category Proportions

Based on results presented in Section II, we conclude that test boat catches are representative of angler catches for the following reasons:

- Mean length of legal-size marked fish caught by test fishing was not significantly different from angler caught fish measured in dockside creel surveys for eight out of nine area/year comparisons.
- Length frequency distributions were not significantly different for legal-size marked fish caught by test fishing and anglers.
- Mean length of fish caught by test fishing showed significant differences between areas all years and therefore clearly captured the differences in the available pool of fish between the two areas.
- Test fishing mark rate was more similar to VTR mark rate than it was to the creel survey mark rate.
- Test fishing mark rate was significantly different from creel in 5 out of 10 year/area comparisons. Since angler catches are subject to recall bias, this is an expected result.
- Mark rate of legal-size fish caught by test fishing was not significantly different from mark rate of fish reported on VTRs in 9 out of 10 year/area comparisons.
- Test fishing mark rate was not consistently higher or lower than mark rates of VTRs and creel surveys suggesting that it is not uniformly biased either high or low.
- VTR data is subject to clumped and/or patchy distribution throughout the season whereas test fishing data is collected throughout the season and responds to catch rate.
- Confidence intervals for proportions in the four mark-status/size categories were tighter for test fishing versus VTRs.
- Proportions in the four mark-status/size categories were not significantly different from VTR proportions in 7 out of 10 year/area comparisons.

## FRAM

FRAM predicted too few marked fish encounters and mortalities and too many unmarked encounters and mortalities for this fishery. FRAM input parameters unmarked retention error was too high and marked release error is too low. FRAM assumes no sublegal-size fish are retained, when clearly there is unmarked sublegal-size retention error and marked sublegal-size retention.

## CONCLUSIONS

## State and Tribal Objectives

Prior to implementation of the 2003 selective Chinook fishery, fisheries managers identified a number of questions about the magnitude and impacts of selective fisheries that needed to be addressed by a monitoring and evaluation program. Although additional questions were identified, this monitoring and evaluation program was not intended to address those additional questions. Questions that are addressed include:

## Sampling Intensity

## Can the sampling program adequately measure effort and harvest?

The use of the Murthy type estimator for quota management worked well with no changes needed.

## How would we measure mark rate?

We measured mark rate by creel survey, Voluntary Trip Reports and test fishing. Test fishing provided the most reliable unbiased method of determining both mark rate and sublegal-size to legal-size proportions. Creel surveys are subject to substantial error and bias and were the least desirable method. Voluntary Trip Reports can provide information on mark rate and sublegal to legal ratios in lieu of test fishing, although the data is likely to have errors and biases, especially at low sample size. Use of VTRs in a destination area like Sekiu requires additional effort to successfully collect good data.

## Fishery Description

## What level of effort would occur?

Opening of this selective Chinook fishery did not lead to effort levels that are substantially higher than historical levels and in fact, in the Area 5 and 6 selective Chinook fisheries, effort was well below historical levels.

## What would be the mark rate?

The mark rate during this fishery ranged from about 40 to 60 percent, and for legal-size fish from about 35 to 65 percent, increasing over time.

## How many sublegal-size fish would be caught and released?

The proportion of sublegal-size fish in Area 5 dropped from 0.54 in 2003 to 0.33 in 2007. Few sublegal-size Chinook were caught in Area 6, never exceeding 0.06 of the catch.

## How many unmarked fish would be released for every fish landed?

For both areas combined, the number of fish released per landed dropped during the five years of fisheries from 4.2 to 2.0 .

## How many mortalities would occur in this fishery?

Total fishing related Chinook mortalities ranged from 2,839 to 6,193.

## What stocks of fish would be caught?

Puget Sound and Columbia River origin stocks comprise the bulk of the fishery. Very few Strait of Juan de Fuca origin stocks are caught in this fishery.

## What would be the impact to the coded wire tag program?

Very few DIT fish are caught in this fishery and the effect on the DIT mark rates appears undetectable.

## What would angler compliance be?

Angler compliance exceeded $90 \%$ at all times. Sublegal-size retention was high in 2007 and additional resources should be directed to ensure continued compliance with the minimum size regulation.

## Use of FRAM to Predict Selective Fishery Impacts

## Encounters/Landed Catch

Since the Area 5 and 6 Chinook fishery is modeled as a quota, deviations of FRAM predicted encounters and catches from creel encounters and catches are not due to inaccurate fisheries scalars. Rather, FRAM inputs of mark release error, unmarked retention error, as well as stock and age specific abundances are responsible for the differences. Mark release error and unmarked retention error are addressed below. Stock and age specific abundances of unmarked and marked Chinook are developed outside of the FRAM model. Unmarked and marked stock composition for FRAM can be compared to DNA stock composition after DNA samples have been analyzed.

Excluding 2005 since the quota was not achieved, FRAM total encounter estimates were generally higher than creel total encounter estimates using either method 1 or 2 . They were on average $16 \%$ higher than method 1 estimates and $64 \%$ higher than method 2 estimates. Compared to method 1, FRAM tends to slightly underestimate marked encounters and significantly overestimate unmarked encounters.

FRAM estimates of landed catch should exactly match creel estimates, because the fishery is modeled as a quota. Due to management inaccuracies the FRAM estimate of landed catch is slightly lower than the creel estimate ( $2 \%$ average). Similar to total encounters, FRAM tends to underestimate marked catch and overestimate unmarked catch.

FRAM is not designed to estimate sublegal landed catch. Although this parameter is not estimated in FRAM, sublegal retained catch is accounted for in the quota as retained catch and ultimately leads to the fishery ending sooner.

## Unmarked Retention Error (legal-unmarked kept/legal-unmarked encountered):

FRAM uses a rate of $8 \%$ to calculate the predicted number of unmarked legal-size Chinook that are retained in a selective fishery. This rate is applied to the number of unmarked legal fish encountered. The calculation of unmarked retention error in the creel survey varies depending on whether method 1 or method 2 is used to estimate Chinook encounters. The average method 1 and method 2 estimates of unmarked retention error are $0.7 \%$ and $0.9 \%$ respectively, with no single year/method exceeding $2 \%$. The FRAM value of $8 \%$ is significantly higher than the creel values. It was originally selected to provide a generous estimate of this parameter until more data could be collected to substantiate this value.

## Mark Release Error (legal-marked released/legal-marked encountered):

FRAM uses a value of $6 \%$ as the estimate of Chinook legal-marked release error in selective fisheries. Creel estimates of legal-marked release error are produced only via the method 1 approach, because method 2 assumes that anglers retain all legal-marked Chinook encountered. Method 1 estimates of the legal marked release error range from $24 \%$ to $37 \%$, with an average value of $28 \%$. VTR estimates for this parameter average $5 \%$.

## Test Fishing Encounters

FRAM models 150 encounters per test fishing boat and month. The average number of actual test fishing encounters per area and month was 157 in Area 5 and 71 in Area 6.

## State Objectives

## How would anglers respond to the fishery and would they be satisfied with the mark rate?

Effort levels were generally higher than for years of short-duration, quota managed, non-selective fisheries. Anglers appear satisfied with the mark rate of legal-size fish.

## Other Questions and Issues

## Method 1 versus Method 2

Though it is impossible to know with certainty the true number of Chinook salmon encountered in a particular fishery, preceding considerations suggest that both Method 1 and Method 2 have the potential to yield biased estimates of this important fishery parameter. For this reason, it may be more productive to define the set of conditions under which one method is expected to yield better (i.e., less biased) estimates than the other and/or determine defensible means for adjusting for measurable biases when they occur.

## Length and Duration of Monitoring

Monitoring and evaluation of this fishery occurred for five years. Very little additional knowledge was gained after the first three years. The range of effort and harvest was established by the first 3 years, with 2003 representing a good fishing year and 2005 representing a poor fishing year. The ability of the sampling program to estimate effort, harvest and releases within required precision levels was demonstrated with the first year of monitoring. The ability of test fishing to effectively mimic the fleet was demonstrated with the first year of sampling, and again in the second year after changes were made in an attempt to better mimic the fleet. While the ratio of released fish to harvested fish continued to drop throughout the duration of the fisheries, even in 2003, the first year of the fishery, the observed impacts to unmarked Chinook were less than predicted by FRAM. That is, conservation objectives for this fishery were met during the first year of the fishery and every year thereafter. Catch per unit effort is clearly a representative measure of the quality of fishing in Areas 5 and 6 . Since C/f can be computed from baseline sampling, it could be used to monitor gross changes in the fishery in lieu of the intensive sampling that has occurred to date. Major effort changes are also picked up in a relative scale during baseline sampling. If significant changes in $\mathrm{C} / \mathrm{f}$ and effort are noted during baseline sampling, managers can then decide if additional intensive monitoring is required to investigate if the fishery is no longer within predicted FRAM impacts.

## Conservation Objectives

Finally, it is important to highlight that despite questions that might remain about selective fishery mortality rates, multi-year impacts, effects on the coded wire tag program, etc. this fishery consistently met the pre-season conservation objectives for unmarked Chinook, i.e. the estimated mortalities of unmarked Chinook were less than predicted in FRAM models used during the pre-season planning process for every year of the fishery.

## RECOMMENDATIONS

- With the existing sampling program and Methods 1 and 2 as starting points, WDFW and tribal co-managers should work towards a mutually agreeable encounters and mortalities estimation framework.
- The dockside interview process should be modified to quantify the extent of intentional legal-marked Chinook release activity for the entire recreational fleet. This assessment will yield additional insight on the utility of the Method-2 estimator and may provide a representative means for adjusting M2 estimates for release-related bias. A caveat to this approach is that it adds a new assumption to the M2 approach (i.e., that angler-reported legal-marked Chinook releases are accurate; as legal-marked Chinook release is a low frequency but memorable event, this may be of minor consequence).
- In areas with sufficient test boat samples, VTRs add relatively little additional information. Resources directed at the VTR program are probably better utilized elsewhere (e.g. test fishing) when test fishing samples are adequate. In contrast, when test fishing samples are low and fishing catch rate is high, VTRs can be a significant source of supplemental information. Successful implementation of a VTR program in a "destination" area such as Sekiu is problematic. We recommend relaxing standards of training for participants of the VTR program in these locations, providing VTR instructions and data sheets to anglers in the morning prior to their trip, and utilizing data from any anglers returning forms. Given the aforementioned caveats, VTRs can provide useful information on mark rate and sublegal-size to legal-size ratios when test fishing is not conducted.
- Mean lengths of fish caught by test fishing and anglers were not significantly different even though the proportion of fish caught while using downriggers during test fishing was higher than the proportion of Chinook encountered while using using downriggers by the fleet. This suggests that the method of fishing was not biasing the size of fish encountered by test fishing. Therefore we recommend utilizing the most efficient method of catching fish on test boats in order to boost sample size and increase precision rather than attempting to prevent bias by adjusting methods to match anglers.
- With the high mark rate of legal-size Chinook observed in Area 6 (40-60\%) and low rate of sublegal encounters, this is perhaps the lowest bycatch recreational selective fishery in
the state. As no local stock CWTs have been observed in the Area 6 fishery and the number of fish released per harvested in very low, this fishery would be a very good choice for expanded angler opportunity.
- Very little additional information was gained relative to evaluating the magnitude of the Areas 5 and 6 selective Chinook fisheries nor the effectiveness the monitoring program after the third year of implementation. Therefore we recommend a maximum of 3 years of monitoring for short-duration (less than 3 months) selective fisheries unless inter-year variation suggests additional years of monitoring are necessary. Additional intensive monitoring should occur if significant changes are observed in C/f, effort, or release estimates as measured by baseline sampling.
- Adjust the FRAM input parameter for unmarked retention error to a value of $2 \%$ to calculate the predicted number of unmarked legal-size Chinook that are retained in a selective fishery.
- Defer a decision on a new value for mark release error pending resolution on methodology. We expect the range for this parameter to be between 5\% (VTR) and $28 \%$ (creel method 1).
- Continue to model 150 Chinook encounters per test fishing boat and month.
- Since the changes necessary to model sublegal retained catch in FRAM require a major programming effort and since sublegal catch is accounted for in the quota, no FRAM change to model sublegal retention is proposed.

## ACKNOWLEDGEMENTS

The conceptual development and preparation of this document was a collaborative effort, with contributions from several WDFW staff. Led by Pat Pattillo, this team included Mark Baltzell, Angelika Hagen-Breaux, Larrie LaVoy, Doug Milward, Peter McHugh, Laurie Peterson, Kristen Ryding, and Steve Thiesfeld. Our efforts were also shaped and enhanced by feedback given by tribal biologists. Through discussions at face-to-face and teleconference meetings and based on thorough reviews of earlier report drafts, contributions were made by: Rebecca Bernard (Swinomish Tribe), Scott Chitwood (Jamestown S'Klallam Tribe), Robert Conrad (NWIFC), Cindy Gray (Skokomish Tribe), Paul Hage (Muckleshoot Indian Tribe), Bob Hayman (Skagit River System Cooperative), Nick Lampsakis (Point No Point Treaty Council), Hap Leon (Makah Indian Tribe), Bill Patton (NWIFC), Andy Rankis (NWIFC), Kit Rawson (Tulalip Tribes), and Craig Smith (Nisqually Indian Tribe).

Our multi-year review would not have been possible without the contributions of the many individuals directly involved in the coordination and sampling of the Areas 5 and 5 fisheries. The efforts of Larry Bennett and Connie Warren, and their crews resulted in the reliable and timely collection of fishery data during both seasons. In Olympia, Lee Dyer provided substantial help with personnel logistics and support services for the project; Karen Kloempken managed WDFW's sampling databases and provided finalized post-season data for evaluation; and Mark Baltzell helped plan and coordinate all sampling efforts during both seasons.

## APPENDICES

## Appendix A. Estimating season-wide mark-selective fishery impacts

List A1. Variable definitions and equations associated with Figure A1.
Below are definitions and equations for all quantities used in estimating total mark-selective fishery impacts under "Method 1". The sequence in the list builds from estimators (and variances) of encounters-by-class (i.e., size/mark-status groups) for each marine area (spatial strata) to season-wide fishery-impact estimates. Where appropriate, estimation differences leading to "Method-2" estimates of fishery impacts are identified and are denoted by $\ddagger \ddagger$. Regarding notation: i) symbols follow those in Figure A1; ii) estimated quantities appear in italics; and iii) constants (with an assumed variance of zero) are depicted in bold-faced, italicized font.

## A. Total and class-specific encounters estimation:

The first step towards quantifying mark-selective fishery impacts by size/mark-status class is the apportioning of Murthy-based estimates of total Chinook encounters (the sum of retained and released fish; Encounters) in a given stratum $i$ to the appropriate group using encountercomposition data collected in the WDFW test fishery (Test-fishery Encounter Composition).

## Encounters

$E_{i}=\quad$ Estimated total Chinook encounters for stratum $i$, inclusive of retained and released individuals from all mark-status groups ( $N_{\mathrm{MK} i}=$ marked-retained, $N_{\mathrm{UK} i}=$ unmarkedretained, $N_{\mathrm{MR} i}=$ marked-released, and $N_{\mathrm{UR} i}=$ unmarked-released), released Chinook of unknown mark status ( $N_{\mathrm{unkR}}$ ), and apportioned unidentified salmon [ $N_{\mathrm{AUS}}$, i.e., unidentified (to species) released salmonids that may have been Chinook; apportioned by identified-released proportions] derived using the Murthy estimator. $E_{i}$ and its variance are estimated as:

$$
\begin{gather*}
E_{i}=N_{\mathrm{MK} i}+N_{\mathrm{UK} i}+N_{\mathrm{MR} i}+N_{\mathrm{UR} i}+N_{\mathrm{UnkR} i}+N_{\mathrm{AUS} i}  \tag{1}\\
\operatorname{var}\left(E_{i}\right)=\operatorname{var}\left(N_{\mathrm{MK} i}\right)+\operatorname{var}\left(N_{\mathrm{UK} i}\right)+\operatorname{var}\left(N_{\mathrm{MR} i}\right)+\operatorname{var}\left(N_{\mathrm{URR} i}\right)+  \tag{2}\\
\operatorname{var}\left(N_{\mathrm{UnkR} i}\right)+\operatorname{var}\left(N_{\mathrm{AUS} i}\right)^{1}
\end{gather*}
$$

$\ddagger \ddagger$ For Method-2, the total encounter estimate, $E_{i}$, is obtained by: 1$)$ combining the marked-legal retention
estimate $\left(K_{\mathrm{LM}}\right)$ and the test-fishery-based estimate of the proportion of at-large Chinook that are marked
and of legal size $\left(p_{\mathrm{LM} i} ;\right.$ defined in 3 and 9 below and 2$)$ assuming that anglers retain all legal-size, marked
Chinook $\left[i . e ., E_{i}=K_{\mathrm{LM}} / p_{\mathrm{LM} i}\right.$, with $\left.\operatorname{var}\left(E_{i}\right)=\left(K_{\mathrm{LMi}}{ }^{2} / p_{\mathrm{LM} i}^{2}\right)^{*}\left(\operatorname{var}\left(K_{\mathrm{LM}}\right) / K_{\mathrm{LM} i}^{2}+\operatorname{var}\left(p_{\mathrm{LM}}\right) / p_{\mathrm{LM}}{ }^{2}\right)\right]$. This
estimate is used in all subsequent Method- 2 computations in a manner identical to Method-1 $E_{i}$ unless
specified otherwise.

[^0]
## Test-fishery Encounter Composition

$p_{\mathrm{LM} i}=$ the test-fishery estimate of Chinook catch proportion comprised of legal (L), marked (M) individuals in stratum $i$
$p_{\mathrm{LU} i}=$ the test-fishery estimate of Chinook catch proportion comprised of legal (L), unmarked (U) individuals in stratum $i$
$p_{\mathrm{SM} i}=$ the test-fishery estimate of Chinook catch proportion comprised of sublegal (S), marked (M) individuals in stratum $i$
$p_{\mathrm{SU} i}=$ the test-fishery estimate of Chinook catch proportion comprised of sublegal (S), unmarked (U) individuals in stratum $i$

For each $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), test-fishery $p_{X Y i} \mathrm{~S}$ and their variances are estimated as:

$$
\begin{align*}
& p_{X Y i}=N_{X Y i} / \Sigma N_{X Y i}, \text { and }  \tag{3}\\
& \operatorname{var}\left(p_{X Y i}\right)=\left[p_{X Y i}{ }^{*}\left(1-p_{X Y i}\right)\right] /\left(n_{i}-1\right),
\end{align*}
$$

where $n_{i}=$ the total number of fish encountered by test boats in stratum $i$.

## Encounters by Size/Mark-status Class

$E_{\mathrm{LM} i}=$ estimated legal (L), marked (M) encounters in stratum $i$
$E_{\mathrm{LU} i}=$ estimated legal (L), unmarked (U) encounters in stratum $i$
$E_{\mathrm{SM} i}=$ estimated sublegal (S), marked (M) encounters in stratum $i$
$E_{\mathrm{SU} i}=$ estimated sublegal (S), marked (U) encounters in stratum $i$
For each $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), apportioned encounters $E_{X Y i}$ and a conservative estimate of its variance (assuming $\mathrm{p}_{\mathrm{XYi}}$ and $\mathrm{E}_{\mathrm{XYi}}$ are independent estimates) are obtained from:
(6) $\quad \operatorname{var}\left(E_{X Y i}\right)=\operatorname{var}\left(E_{i}\right)^{*} p_{X Y i}^{2}+E_{i}^{2} * \operatorname{var}\left(p_{X Y i}\right)$
$\ddagger \ddagger \operatorname{var}\left(E_{X Y i}\right)$ (i.e., equation 6) includes an additional covariance component [i.e., $\left.\operatorname{var}\left(E_{i}\right) * \operatorname{var}\left(p_{X Y i}\right)\right]$ for
Method-2 estimates of apportioned encounters given that $E_{i}$ is derived from test-fishery data.

## B. Estimating Retained and Released Numbers by Size/Mark-status Class:

Before mortality can be estimated for each class, the number of fish retained and released must be estimated. Class-specific retention estimates are obtained by apportioning Murthy estimates of marked and unmarked Chinook retained in each stratum $i$ to size classes (Apportioned Estimates of Retention to Size Classes); this is achieved using proportions estimated during dockside creel surveys (Dockside Observations for Apportioning Retained Catch to Class).

Releases are then estimated as the difference between class-specific total encounters and retention (Estimating Release Numbers by Class).

## Dockside Observations for Apportioning Retained Catch to Class

$d_{\mathrm{LMK}}=$ the estimated proportion of retained (kept, K), marked (M) Chinook salmon that were legal (L); based on season-wide dockside observations of marked Chinook (as is $d_{\text {SMK }}$ )
$d_{\text {SMK }}=$ the estimated proportion of retained (kept, K), marked (M) Chinook salmon that were sublegal (S)

The proportion of retained, marked fish in size class $X(X=\mathrm{L}$ or S$)$ and its variance are estimated as:
(8) $\operatorname{var}\left(d_{X \mathrm{MK}}\right)=\left[d_{X \mathrm{MK}} *\left(1-d_{X \mathrm{MK}}\right)\right] /\left(\Sigma n_{X \mathrm{MK}}-1\right)$,
where $\Sigma n_{X M K}$ and $n_{X M K}$ are season-wide total dockside counts of marked fish and the subset of marked fish in size-class $X$, respectively.
$d_{\text {LUK }}=$ the estimated proportion of retained (kept, K ), unmarked (U) Chinook salmon that are legal (L) ; estimated from season-wide dockside observations of unmarked Chinook (as is $p_{\text {SUK }}$ )
$d_{\mathrm{SUK}}=$ the estimated proportion of retained (kept, K), unmarked (U) Chinook salmon that are sublegal (S)

The proportions of retained, unmarked fish belonging to legal and sublegal size classes are estimated as above (7 and 8) but using season-wide dockside observations on unmarked (U), not marked Chinook salmon.

## Apportioned Estimates of Retention to Size Classes

$K_{\mathrm{LM} i}=$ estimated number of legal (L), marked (M) Chinook kept in stratum $i$
$K_{\mathrm{LU} i}=$ estimated number of legal (L), unmarked (U) Chinook kept in stratum $i$
The number of kept, marked encounters, marked fish in size class $X$ (legal or sublegal) and its variance is estimated as:
(9) $\quad K_{X \mathrm{M} i}=d_{X \mathrm{MK}} * N_{\mathrm{MK} i}$
(10) $\quad \operatorname{var}\left(K_{X M i}\right)=\operatorname{var}\left(N_{\mathrm{MK} i}\right)^{*} d_{X \mathrm{MK}}{ }^{2}+N_{\mathrm{KM} i}{ }^{2} * \operatorname{var}\left(d_{\mathrm{XMK}}\right)-\operatorname{var}\left(N_{\mathrm{MK} i}\right)^{*} \operatorname{var}\left(d_{X \mathrm{MK}}\right)$
where $d_{X \mathrm{MK}}$ and its variance are from 7 and 8 above and $N_{\mathrm{MK} i}$ is the Murthy estimate of retained marked fish for stratum $i$ defined for 1 above.
$K_{\text {SM } i}=$ estimated number of sublegal (S), marked (M) Chinook kept in stratum $i$
$K_{\mathrm{SU} i}=$ estimated number of sublegal (S), unmarked (U) Chinook kept in stratum $i$

The number of retained, unmarked fish belonging to legal and sublegal size classes is estimated as above (9 and 10) using unmarked fish proportions and season-wide Murthybased retention estimates (and variances).

## Estimating Release Numbers by Class

$R_{\mathrm{LM} i}=$ estimated number of legal (L), marked (M) Chinook released in stratum $i$
$R_{\mathrm{LU} i}=$ estimated number of legal (L), unmarked (U) Chinook released in stratum $i$
$R_{\mathrm{SM} i}=$ estimated number of sublegal (S), marked (M) Chinook released in stratum $i$
$R_{\mathrm{SU} i}=$ estimated number of sublegal (S), unmarked (U) Chinook released in stratum $i$
For each size/mark-status class $X Y$ combination ( $X=\mathrm{L}$ and S and $Y=\mathrm{M}$ or U ), the number fish encountered and released is estimated as the difference of total size/markstatus class encounters ( $E_{X Y i}$ ) and retention ( $K_{X Y i}$ ) in stratum $i$. The estimator and its variance are:
(11) $R_{X Y i}=E_{X Y i}-K_{X Y i}$
(12) $\quad \operatorname{var}\left(R_{X Y i}\right)=\operatorname{var}\left(E_{X Y i}\right)+\operatorname{var}\left(K_{X Y i}\right)$
$\ddagger \ddagger$ For Method-2, $R_{\mathrm{LM} i}$ is assumed to be zero with zero variance (i.e., anglers retain all legal-size, marked fish); all other $R_{X Y i}$ are estimated using equations 11 and 12, but with Method-2-specific $E_{X Y i}$ s.

## C. Estimating Total (and Class-specific) Season-wide Mortality:

The final step towards quantifying mark-selective fishery impacts is the application of assumed mortality rates (Assumed Mortality Rates for Retained and Released Chinook) to class-specific retention and release estimates.

## Assumed Mortality Rates for Retained and Released Chinook

$\boldsymbol{m}_{\mathbf{K}}=$ retention mortality rate, $100 \%$ for all retained Chinook
$\boldsymbol{s f m _ { \mathrm { L } }}=$ release mortality rate for legal (L) Chinook, assumed to be a constant $15 \%$
$\boldsymbol{s f m _ { \mathrm { S } }}=$ release mortality rate for sublegal (S) Chinook, assumed to be a constant $20 \%$

## Retention-mortality Estimates

$M_{\text {LMKi }}=$ estimated number of mortalities due to direct harvest of legal $(L)$, marked ( $M$ ) Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\mathrm{LM} i}$ given that $m_{\mathrm{K}}=1.00$ (i.e., $M_{\mathrm{LMK} i}=K_{\mathrm{LM} i}{ }^{*} \boldsymbol{m}_{\mathrm{K}}$ ).
$M_{\text {LUK } i}=$ estimated number of mortalities due to direct harvest of legal $(L)$, unmarked ( $U$ )
Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\mathrm{LU} i}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\mathrm{LUK} i}=K_{\mathrm{LU} i}{ }^{*} \boldsymbol{m}_{\mathbf{K}}$ ).
$M_{\text {SMK } i}=$ estimated number of mortalities due to direct harvest of sublegal ( $S$ ), marked ( $M$ )
Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\text {SMi }}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\text {SMK } i}=K_{\text {SMi }}{ }^{*} \boldsymbol{m}_{\mathbf{K}}$ ).
$M_{\text {SUK } i}=$ estimated number of mortalities due to direct harvest of sublegal $(S)$, unmarked ( $U$ ) Chinook in stratum $i$; the point estimate and variance are equivalent to $K_{\text {SUi }}$ given that $m_{\mathrm{K}}$ $=1.00$ (i.e., $M_{\mathrm{SUK} i}=K_{\mathrm{SU}}{ }^{*} \boldsymbol{m}_{\mathbf{K}}$ ).

## Release-mortality Estimates

$M_{\text {LMR } i}=$ estimated number of post-release, fishery-related mortalities of encountered legal ( $L$ ), marked ( $M$ ) Chinook in stratum $i$
$M_{\text {LUR } i}=$ estimated number of post-release, fishery-related mortalities of encountered legal ( $L$ ), unmarked ( $U$ ) Chinook in stratum $i$
$M_{\text {SMR } i}=$ estimated number of post-release, fishery-related mortalities of encountered sublegal $(S)$, marked ( $M$ ) Chinook in stratum $i$
$M_{\text {SUR } i}=$ estimated number of post-release, fishery-related mortalities of encountered sublegal ( $S$ ), unmarked $(U)$ Chinook in stratum $i$

An estimate of release mortality for size/mark-status class $X Y(X=\mathrm{L}$ or $\mathrm{S}, Y=\mathrm{M}$ or U$)$ in stratum $i$ and its variance is obtained from:

$$
\begin{align*}
& M_{X Y \mathrm{R} i}=R_{X Y Y} * s f m_{Y}  \tag{13}\\
& \operatorname{var}\left(M_{X Y \mathrm{R} i}\right)=\operatorname{var}\left(R_{X Y i}\right) * s \operatorname{sm}_{Y}{ }^{2} \tag{14}
\end{align*}
$$

## Season-wide Total and Class-specific Mortality Estimation

$M_{\text {total }}=$ season-wide Chinook mortality due to the selective fishery; this parameter and its variance $\left[\operatorname{var}\left(M_{\text {total }}\right)\right]$ are computed as the sum of all retention $\left(M_{X Y \mathrm{~K} i}\right)$ and release mortality ( $M_{X Y \mathrm{R} i}$ ) estimates and variances, respectively, for the $X Y(X=\mathrm{L}$ or $\mathrm{S}, Y=\mathrm{M}$ or U) size/mark-status groups.

The standard error (SE), coefficient of variation (CV), and 95\% confidence interval about $M_{\text {total }}$ (and all other parameters $\theta$ defined herein) are obtained from:
(16) $\mathrm{CV}(\theta)=[\mathrm{SE}(\theta) / \theta] * 100$
(17) $95 \% \mathrm{CI}=\theta \pm 1.96 * \operatorname{SE}(\theta)$

Figure A1 (Next Page). Graphical representation of the estimation approach used to quantify season-wide encounters and mortalities by size/mark-status category for the Areas 5/6 markselective Chinook fishery. Boxes depict abundance estimates (encounters, mortalities) whereas the mathematical operations depicted on intermediate connector lines are estimator formulae for subsequent boxes (moving from left to right). Gray ovals represent points in the total encounter and mortality estimation sequence where Methods 1 and 2 diverge. Variable and parameter names, complete formulae, and variances (where appropriate) are defined in List A1. Boldfaced, italicized symbols are constants, all others are estimated quantities. Total stratum mortality is the sum of $M_{\mathrm{K} i}$ and $M_{\mathrm{R} i}$; total fishery (combined $5 / 6$ ) mortality is simply the sum all $M_{\mathrm{K} i}$ and $M_{\mathrm{R} i} \mathrm{~S}$.

## Appendix B. Discussion of weighting methods

During the five years of the fishery, we have used two methods to calculate proportions of Chinook caught by test fishing that were in the four mark status/size categories (legal-size marked, legal-size unmarked, sublegal-size marked and sublegal-size unmarked). We initially calculated unweighted proportions, i.e. season-long proportions. Based on comments received on draft reports, we started weighting the proportions weekly by the percent of catch occurring each week, and calculating weighted proportions. These weighted proportions were used in all previous reports, despite issues that have arose with their use. For this report, we have recalculated unweighted, season-long proportions for each year after examining mortality estimates generated using unweighted proportions, proportions weighted by catch, and proportions weighted by encounters. Our reasons for using unweighted proportions are as follows:

1. The use of season-long proportions shores-up the information on stock composition in weeks of with limited or no data. The underlying assumption of this method is that stock compositon with regard to size and mark status is constant across the season. This assumption is difficult to test in practice for the same reason that we propose using season-wide stock compostion estimates; the data are limited for portions of the season.
2. During some years, test boat (or combination test boat and VTR) catches have been zero for one or more weeks. To remedy this problem, we have had to truncate the weighted catches to only those weeks with actual data, thereby adding error and bias to the weighted proportions.
3. Confidence limits for unweighted mortality estimates encompassed the estimates weighted by catch and estimates weighted by encounters for all years and each of the four mark status/size categories (Figures A2 and A3).
4. Weighted estimates are less precise than the un-weighted counterparts (Figures A2 and A3) and the differences between weighted and unweighted estimates were small. Although, weighed estimates may be less biased than unweighted estimates, the mean squared error of unweighted estimates is smaller. Further, the differences between weighting methods is less than the difference between whether Method 1 or Method 2 is used to estimate total encounters (Figures A2 and A3).

Figure A2. Comparison of legal-size Chinook mortalities in the Area 5 and 6 selective Chinook fisheries based on weighting methods and encounter estimation methods (Method 1, M1 and Method 2, M2).

Figure A3. Comparison of sublegal-size Chinook mortalities in the Area 5 and 6 selective Chinook fisheries based on weighting methods and encounter estimation methods (Method 1, M1 and Method 2, M2).

## Appendix C. Analytical assumptions

Analytical assumptions required for estimating catch, effort, and mortality for the Areas 5 and 6 selective Chinook fishery under WDFW's selective fishery monitoring approach.

| Assumption Number | Description | Tested previously | Likelihood of violation | Likely importance | Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Assumption 1 | Boat surveys provide unbiased estimates of access-site size measures and out-of-frame effort proportions | N | Low | High | Indirect evaluations suggest the latter aspect of this assumption (i.e., regarding the out-offrame proportion) is true in a relative sense (WDFW unpublished data). |
| Assumption 2 | Relative angling effort originating from a particular site (i.e., site-size) is proportional to catch landed at that site | Y | Low | Moderate | Simulations by Conrad and Alexandersdottir (1993) demonstrate that mis-specification of size measures leads to precision but not bias issues. |
| Assumption 3 | All anglers exiting the fishery are interviewed and accurately report their catch (missed boats are dealt with analytically assuming average values) | N | Moderate | High | The accuracy of angler-reported encounters, particularly releases during high-encounter periods, is uncertain but important |
| Assumption 4 | C/F does not differ between in-frame and out-of-frame access sites | N | Unknown | Unknown | Likely difficult, if not impossible, to test. |
| Assumption 5 | Anglers retain all legal-marked Chinook encountered | N | High | Low | Empirical estimates for avid anglers suggest intentional legal-marked release rates are $\sim 10 \%$; unintentional legal-marked release is unknown. |
| Assumption 6 | Test-fishery and private-fleet encounter composition (I.e., frequency by size/markstatus class) is identical. | N | Low | High | Preliminary analyses of length-frequency distributions, age-data, and overall mark rates suggest both test fishers and the private fleet are accessing a similar pool of fish. |

## Appendix L. Estimated mortality of unmarked DIT Chinook due to catch and release mortality

Observed number of Double Index Tagged (DIT) Chinook kept by anglers, and the estimated mortality of unmarked DIT Chinook due to catch and release mortality, during the Chinook Selective Fisheries in Marine Areas 5 and 6, 2003 through 2006.

2003 Recoveries

| Hatchery | Brood Year | DIT <br> Tagged fish Observed | Estimated Harvest of Marked DIT fish | Estimated Angler Releases of UnMarked DIT fish | Estimated <br> Mortality of Unmarked DIT fish | Variance of Estimated Mortality of DIT Fish | Standard Error of Estimated <br> Mortality of DIT Fish |
