Fish Program Report Number FPA 09-04

July 2009

## Abstract

This report summarizes activities by the Washington Department of Fish and Wildlife's (WDFW) Lower Snake River Hatchery Evaluation Program for the period 16 April 2006 through 15 April 2007. We have also included the Statistical Analysis of 2006 Lower Granite Dam Fall Chinook Run Reconstruction report funded by the Pacific Salmon Commission’s Southern boundary Restoration and Enhancement Fund in order to make it more widely available.

In 2006, WDFW collected 3,679 fish at Lyons Ferry Hatchery (LFH) and Lower Granite Dam (LGR) for broodstock, monitoring and evaluation of our hatchery releases, and to estimate the run size to LGR. This was the fourth year that natural origin fish were integrated into our broodstock. Of the total number of fish contributing to production, $81.1 \%$ were Lyons Ferry hatchery origin, $12.2 \%$ were natural origin, $5.1 \%$ were out-of-basin stray hatchery fish based on scale readings, and $1.6 \%$ were of unknown origin.

A total of 2,819,004 green eggs were taken at Lyons Ferry Hatchery, well below the full production goals listed in the 2005-2007 United States v. Oregon Management Agreement. Survival from green to eye-up was $96.8 \%$ with an estimated $1.1 \%$ additional loss to ponding.

WDFW released brood year 2005 (BY05) sub-yearlings directly from LFH (202,211 fish), two releases (200,820 and 211,508 fish) into the Snake River near Couse Creek Boat Launch (Rkm 253.7), and two releases ( 200,432 and 208,733 fish) directly into the Grande Ronde River near the mouth of Cougar Creek. The first Couse Creek release was part of an ongoing direct vs. acclimated study (released from the Captain John acclimation site). An accidental fry (BY05) release of 71,000 fry at 181 fpp occurred on 4 April at LFH. The LFH also released 503,160 yearling fall Chinook (BY05) into the Snake River on site from 2-6 April 2007. Releases of fish into the Snake Basin from 2000 through 2007 are provided.

We surveyed the Tucannon River by foot, covering $91 \%$ of the historical spawning area of fall Chinook. We estimated 449 fall Chinook and 11 summer Chinook escaped to the Tucannon River, producing an estimated 153 redds. The return to the Tucannon River was estimated to be $45 \%$ inbasin hatchery fish, $14 \%$ out-of-basin hatchery fish, $30 \%$ natural origin fish, $9 \%$ unknown origin fish (hatchery or wild), and $2 \%$ summer Chinook.

Smolt-to-adult return estimates for broodyears 1999 through 2005 are presented for fish released by WDFW. Yearlings continue to provide a survival advantage over subyearlings although it is highly variable year to year. We present data showing a survival advantage of onstation subyearlings when compared to direct releases into the Snake River near Couse Creek and the Grande Ronde River.

We adjusted harvest estimates of CWT tagged fish by fishery, sample detection type, and tag loss to fully reflect total take of non-tagged, non-clipped, as well as adipose clipped, and CWT tagged fall Chinook. Analysis was done solely on recoveries of fall Chinook released by WDFW and does not include recoveries of LSRCP fish from the Nez Perce Tribe (NPT), fish released from NPT Hatchery, or fish released from Idaho Power Company programs.

Of the WDFW releases, we estimate that 2,844 fall Chinook were taken in fisheries downstream of the Snake River in 2006. By location, fishers in the Columbia River harvested $38 \%$ of the total number harvested and fishers in British Columbia harvested 37\%. By fishery, the British Columbia Troll fishery intercepted $28 \%$ of all fish harvested. This is the first time we have attempted to expand the CWT data in this manner and although it is preliminary, it shows the importance of doing so to fully reflect and understand the harvest component for mitigation.

Outside of the Snake River basin, 25 of Washington's fall Chinook were intercepted at hatcheries or racks and 40 were recovered on spawning grounds. We estimate that 4,827 LFH/Snake River hatchery origin fall Chinook released by WDFW returned to the Snake River.

## Acknowledgments

The Lyons Ferry Fall Chinook Salmon Hatchery Evaluation Program is the result of work by many individuals within the Washington Department of Fish and Wildlife Fish Program. We want to thank all those who contributed to this program.

We would like to thank the Snake River Lab staff: Joe Bumgarner, Jerry Dedloff, Michael Gallinat, Jule Ponti, and Lance Ross. We also thank the Walla Walla Assessment staff for their help.

We thank the personnel at Lyons Ferry Hatchery for their cooperation with sampling and providing information regarding hatchery operations. A special thanks goes to Steve Rodgers, Dick Rogers, and Brandon Kilmer for their assistance with summarizing hatchery data for this report. We appreciate the assistance of Lynn Anderson and crew at the WDFW Tag Recovery Lab. Thanks also to John Sneva (WDFW) who processed our scale samples.

We appreciate the efforts of Jerry Harmon (NOAA Fisheries) and crew at Lower Granite Dam for trapping, tagging, and documenting fall Chinook salmon for transport to Lyons Ferry Hatchery. We also thank Fred Mensik (WDFW) for providing summarized adult fallback data from the juvenile collection facility at Lower Granite Dam. We also thank Dr. Kirk Steinhorst and George Naughton (University of Idaho), and Bill Arnsberg (NPT) for providing information for the fall Chinook run reconstruction at Lower Granite Dam for 2006.

We thank Glen Mendel, Steve Yundt, Andrew Murdoch, and Craig Busak for reviewing this report and providing valuable comments.

Finally, we thank the U.S. Fish and Wildlife Service, Lower Snake River Compensation Plan Office, for providing funding and encouragement for this program.

## Program Objectives

This report summarizes activities by the Washington Department of Fish and Wildlife's (WDFW) Lower Snake River Hatchery Fall Chinook Evaluation Program for the period 16 April 2006 to 15 April 2007. Washington Department of Fish and Wildlife's (WDFW) Snake River Lab (SRL) staff completed this work with Federal fiscal year 2006 funds provided through the U.S. Fish and Wildlife Service (USFWS), under the Lower Snake River Compensation Plan (LSRCP).

Congress authorized the LSRCP in 1976. As a result of that plan, Lyons Ferry Hatchery (LFH) was constructed and has been in operation since 1984 (Figure 1). One objective of the hatchery was to compensate for an annual loss of 18,300 adult (non-juvenile) ${ }^{1}$, Snake River stock, fall Chinook salmon (U.S. Army Corps of Engineers 1975). An evaluation program was initiated in 1984 to monitor the success of LFH in meeting the LSRCP compensation goals and to identify any production adjustments required to accomplish those goals. This mitigation program was modified in the early 1990s by agreement of the United States v. Oregon parties to supplement natural fall Chinook production above Lower Granite Dam (LGR). Currently this is an integrated hatchery program designed to support recovery of the Snake River naturally produced fall Chinook. This action was consistent with the U.S. Endangered Species Act and Washington's Wild Salmonid Policy.

The WDFW has two general goals for its fall Chinook evaluation program: (1) monitor hatchery practices at LFH to ensure quality smolt releases, high downstream migrant survival, and sufficient adult fish contribution to fisheries and escapement to meet the LSRCP compensation goals; and (2) gather genetic information to help maintain the integrity of the Snake River Basin fall Chinook salmon stock (WDF 1994). Our efforts have contributed to evaluating the status of Snake River fall Chinook by monitoring population abundance, spatial distribution, genetics, and life history (sex and age information of returns) as well as by removing strays at LGR on the Snake River to minimize the effects of out-of-basin strays on the population (NMFS 1993). Specific annual program objectives can be obtained from the Snake River Lab Project office.

Figure 1. Lower Snake River Basin showing location of Lyons Ferry Hatchery and major tributaries in the area.

## Broodstock Collection and Management

Fall Chinook are collected at LFH and LGR for broodstock (Appendix A). Each year there is a discrepancy between estimated numbers of fish collected and the numbers of fish processed/ killed (Table 1). The in-season estimate of numbers of fish diverted into the hatchery at LFH is a minimum estimate of the run to LFH. Some of the fish that are trapped at LFH are returned to the river and never used for broodstock (see LFH Trapping Operations below). The discrepancy between the numbers of fish recorded as collected at LGR and the number of fish processed likely occurs because of indistinguishable or overlooked operculum punches (an identifier administered at the LGR fish trap; see below) on fish hauled from LGR. Unaccounted for LGR trapped fish are likely included with processed LFH fish.

Table 1. Number of Chinook initially collected for broodstock from LFH and LGR trapping efforts and how they were accounted for in 2006.

|  | Trap |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Number <br> Location | Collected/Hauled <br> for Broodstock | Processed (killed) | Returned to <br> Snake River | Difference from <br> Number <br> Collected/Hauled |
| 2006 | LFH | 2,521 | $1,961^{\text {a }}$ | 774 | +214 |
|  | LGR | 1,158 | 1106 | 42 | -10 |

${ }^{\text {a }}$ Numbers of fish unaccounted for from LGR are assumed to be mixed in with the LFH trapped fish during processing.

## Lower Granite Dam Trapping Operations

Trapping protocols for each year are available upon request. In general, prior to transport, NOAA Fisheries staff anesthetized the salmon, gathered length and sex data, and marked the fish with a hole in the operculum prior to release upstream or transport. WDFW personnel then hauled fish to LFH in a 5,678 L aerated tank truck. Fall Chinook were trapped from 1 September through 21 November 2006. An automated trapping system shunted fish into the trap four times each hour, resulting in the trap being open $13 \%$ of each hour. In addition, the passive integrated transponder (PIT) tag sort-by-code system was activated and allowed for the trapping of PIT tagged fish encountered that were outside of the scheduled $13 \%$ trapping period.

## LFH Trapping Operations

The majority of broodstock are collected at LFH. The trap at LFH was in operation 24 hours per day from 6 September through 26 November 2006. Counts were made each day for fish retained and fish returned to the river. In some prior years the trap was not operated full time or for the length of the run. During those years, the numbers of fall Chinook presented in our reports reflect only what was trapped and retained, not what the total number of fish would have been if we had trapped without a break in trapping.

We documented 12,010 trapping events of fall Chinook at the LFH trap in 2006 (Figure 2). Minijacks accounted for the majority of trapping events $(9,265)$. We were unable to determine the number of unique (excluding recaptures) fish that were trapped because there is no marking protocol in place at the hatchery trap. We assume that jacks and minijacks were recaptured multiple times.

Figure 2. Number of adult and jack fall Chinook arriving at the LFH trap by date, 2006.

## Hatchery Operations

## Spawning Operations

## Spawning and Egg Take

Spawning began the fourth week in October 2006 and continued for seven weeks. Egg take was substantially less than in previous recent years because of low adult return numbers (Table 2). At spawning, ripe fish were killed and their gametes collected and set aside unmixed. All matings were single male/single female crosses. To determine the origin and brood year of fish spawned, snouts containing wires ${ }^{2}$ were removed from tagged fish, and scales were collected from unmarked/untagged fish (no wire or visible implant elastomer (VIE) tag). During spawning, CWTs were decoded to verify origin prior to matings. Untagged fall Chinook were mated the same day they were spawned. Origins of untagged fish could not be determined until the following week when the results of scale and PIT tag analysis were compiled. The total number of fish spawned prior to culling is listed in Table 3.

${ }^{\text {a }}$ Egg mortality includes eggs destroyed due to positive ELISA values.
${ }^{\text {b }}$ An additional 9,000 eggs from stray females were given to Washington State University.
c Doesn't include loss from 10,000 stray eggs given to University of Idaho. The egg loss from strays was $8.63 \%$ excluding eggs used in fertilization experiments.
${ }^{\mathrm{d}}$ Total eggtake includes eggs from one coho female crossed with a fall Chinook.

Table 3. Spawn dates, numbers of fall Chinook, and eggtake of fish spawned at LFH in 2006. (LFH and LGR trapped fish are combined and jacks are included with males).

| Totals | 8 | $\mathbf{7 8 6}$ | 0 | 31,791 |

${ }^{\text {a }}$ Numbers of fish presented include spawned fish whose progeny were later destroyed.
${ }^{\mathrm{b}}$ Non-viable females - three were not ripe when killed and one had already spawned in the pond. All four were hatchery origin fish.

In an effort to include natural origin fish in our broodstock, untagged fish were also used in the broodstock. This was the fourth year that Snake River natural origin fish were included in the broodstock. To reduce the genetic impact that out-of-basin strays might have on the hatchery fall Chinook population, unknown origin fish (no wire or VIE) were mated with unknown origin fish
(Appendix B). This mating protocol differs from that of previous years where unknown origin fish were mated exclusively to LFH origin fish. In the few instances where there were not enough unknown origin males available to mate with unknown origin females, we used LFH origin males in the matings.

Seventy percent of the broodstock for the fall Chinook program was collected at the LFH trap, although the majority of the unmarked/untagged fish included in our broodstock were trapped at LGR. One hundred and seventeen females, and 73 males of presumed Snake River natural origin (based upon scale readings) were spawned in 2006 ( $12 \%$ of the broodstock). Nearly all ( 185 out of 190) of these natural origin fish were hauled from LGR Dam.

Because of adult holding pond constraints (number and size), only fish from one trapping site are processed each spawning day. To increase flexibility and assure the spawning protocol was followed, we continued the practice of holding semen overnight as a reserve for use on the following day if we were short of ripe males that day. Semen can be held overnight and used the following day with only a slight reduction in viability (SRL, unpublished data). The loss resulting from reduction in viability is much less than if we were unable to fertilize at all. Semen from a predetermined number of ripe males was collected and split into two lots. One lot was used the same day it was collected and the other lot was saved for possible use the following day. Semen held over night was stored in individual plastic bags infused with oxygen and placed in a cooler on dry burlap bags above ice.

We used 776 males once and 5 males twice in the 786 matings from which gametes were retained for production. Following procedures described by Busack (2007) we calculated the effective number of male breeders $\left(\mathrm{N}_{\mathrm{b}, \mathrm{m}}\right)$ at 775 using the following equations:

A reasonable constant-size assumption is that the number of offspring equals the number of egg lots ( $\mathrm{N}_{\text {egg_lots }}$ ). In this case:

$$
\mu_{\mathrm{t}}=\mathrm{N}_{\text {egg_lots }} / \mathrm{N}_{\text {tot }}=786 / 781=1.006
$$

where $\mu_{\mathrm{t}}$ is the mean gametic contribution of a randomly chosen individual and $\mathrm{N}_{\text {tot }}$ is the total number of male breeders used. So the male $\mathrm{N}_{\mathrm{b}}$ can be calculated:

$$
\mathrm{N}_{\mathrm{b}, \mathrm{~m}} \approx\left(\mathrm{~N}_{\mathrm{tot}}-1 / \mu_{\mathrm{t}}\right) /\left(\left(\left(\mathrm{N}_{1} \mathrm{~N}_{2}\right) /\left(\mathrm{N}_{1}+2 \mathrm{~N}_{2}\right)^{2}\right)+1\right)=775
$$

where $\mathrm{N}_{1}$ is the number of males used one time and $\mathrm{N}_{2}$ is the number of males used two times.

The effective male breeders is $98.6 \%$ of the census number of males, or $99.2 \%$ of the male $\mathrm{N}_{\mathrm{b}, \mathrm{m}}$ that would have been achieved if enough males had been available to avoid reuse of males. The spawning protocol discourages multiple uses of individual males. There was small reduction in $\mathrm{N}_{\mathrm{b}, \mathrm{m}}$ in 2006, but if the practice were done more, the effect would be commensurately greater.

Of the fish spawned, $81.1 \%$ were LFH origin, $12.2 \%$ were natural origin, $5.1 \%$ were strays based on scale readings, and $1.6 \%$ were of unknown origin because their scales could not be read or the wire was lost (Figure 3). These percentages include fish that were spawned for the Idaho Power

Company (IPC) mitigation agreement as well as the LSRCP program. The majority of hatchery fish spawned came from LFH yearling releases ( $81.4 \%$ of the LFH origin fish). Adults from LFH subyearling releases contributed $18.6 \%$. Jacks (all origins) were used in $4.1 \%$ of the matings. Our spawning protocol indicates that jacks should be included in about $10 \%$ of the matings, but are not to exceed $25 \%$ of the matings.

Figure 3. Origin of Fish Contributing to Broodstock.

Information about processed fish that were not spawned is presented in Table 4. Fish of known or presumed LFH origin have been combined with natural Snake River origin fish in the LFH/Snake River category. Twenty-one of the LFH/Snake River mortalities were of natural Snake River origin, five of the natural origin mortalities were summer run Chinook ( 3 males and 2 females) and the remaining sixteen ( 9 males and 7 females) were fall Chinook. Fish that were killed outright (surplussed) were generally males needed for run composition but not needed for spawning, or strays from other hatcheries. Thirty-four of the surplussed fish had no wire in their snouts. One of these had a left red VIE designating it as LFH origin. Scale analysis of the remaining unmarked/untagged fish indicated 13 were of natural origin ( 10 males, 2 jacks and 1 female that was accidentally crushed in the elevator), eight were of Snake River hatchery origin, eight originated from other hatcheries and four scale samples were unreadable.

Table 4. Weekly summary of mortality and surplus Chinook processed at LFH in 2006. (LFH and LGR trapped fish are combined; jacks are included with males).

| Week <br> Ending | Mortality |  |  |  | Killed Outright |  |  |  |

${ }^{\text {a }}$ Includes known LFH origin (from CWT and/or VIE), and wild or presumed LFH origin (from scale analysis).
${ }^{\mathrm{b}}$ Other/Unknown includes fish from other hatcheries based on CWT or scale analysis, spring and summer Chinook, and fish whose origin could not be determined.

## Fish Returned to River

We trapped more fish at LFH than were needed for run composition estimates. To ensure representative sampling we continued trapping throughout the run. Fish not needed for broodstock or run composition analysis were returned to the Snake River (Table 5).

Fish trapped at LFH were released either upstream of Little Goose (LGO) Dam at Bryan's Landing (Rkm 115.0), or downstream of LGO at Texas Rapids boat launch (Rkm 105.2). In order to document recaptures, fish received a partial caudal clip prior to transport. Thirty jacks from the first haul on 14 November were transported without caudal clips. Hauling and recapture data from previous years indicated fewer fish were recaptured at LFH when released above LGO Dam (Milks et al. 2006). Of the 710 fish that were top-caudal clipped and released at Bryan's Landing in November, four fish were recaptured at LFH ( $0.56 \%$ recapture rate) and three were recovered in carcass surveys on the Tucannon River. Nine top-caudal clipped fish were collected in the $13 \%$ sample at the LGR Dam adult trap. When expanded to account for sample size, an estimated $9.75 \%$ of the fish released at Bryan's Landing ( 69 capture events/710 unique fish hauled and released) had reached LGR Dam by 21 November. Because the LGR trap ceased trapping on November 21, we were not able to document how many more fish continued to move upstream. Fish released at Texas Rapids in December were marked with a bottom-caudal clip. Tucannon River carcass surveys continued through 11 December, however no bottom-caudal-clipped carcasses were recovered.

Excess fish from LGR trapping were transported from LFH and released above LGR Dam at Rooster's Landing (Rkm 221.1). Thirty-seven males and one jack were released on 5 December. They were not marked prior to release. One female (not ripe) and three males were retained until a decision could be made to either hold her for spawning, ship her to NPTH, or return her to the river. On 7 December, all four retained salmon were released above LGR Dam.

Table 5. Release locations, trapping sites, sex, dates, and total number of fish that were hauled back to the Snake River in 2006. Recaptures are included.

| Release location | Trap site | Sex | November |  | December |  | Total |

|  |  | Totals | 343 | 397 | 72 | 4 | 816 |

## Fecundity

We calculated fecundities for several groups of females using methods previously described by Milks et al. (2006). The mean fecundity for fish trapped at LGR and hauled to LFH was 4,178 eggs/female, consisting of hatchery yearling and subyearlings and natural origin fish. For management purposes there are three groups of fish, based upon visual and electronic identification, for which fecundity is of interest: tagged fish (CWT or VIE), unmarked/untagged fish, and adipose fin (AD)-clip only (no wire/no VIE) fish. Tagged fall Chinook (known LFH origin) used in broodstock averaged 3,273 eggs/female and were primarily from yearling releases. Unmarked/untagged fish (hatchery and natural origin) as a whole averaged 4,342 eggs/female, and mean fecundity of the AD-clip only fish, primarily from subyearling releases, was 3,592 eggs/female. Since we are trying to incorporate $10-25 \%$ natural origin gametes into production, it is important to estimate fecundity for natural origin females. Natural origin females averaged 4,369 eggs/female.

In addition to examining the origins of individual fish contributing to LFH broodstock, we also looked at the number and percentage of gametes each fish would have contributed (Figure 4). Females with higher fecundities would contribute more genetically by origin than fish with lower fecundities. Each male was assigned a contribution amount based on the fecundity of the female with which he was mated.

Figure 4. Origin of gametes contributing to LFH broodstock, 2006

## Rearing, Marking, and Transfer

Eyed eggs for the LSRCP program were primarily from LFH x LFH, or natural x natural or Snake River Hatchery origin matings. Eggs were assigned to yearling and subyearling programs based on parental crosses (Table 6). Co-managers in the basin agreed to retain stray gametes in an effort to increase eggtake and meet production levels presented in the United Stats v. Oregon agreement. Because smolt-to-adult returns from yearling releases are consistently greater than those of subyearling releases, progeny of the four wire-tagged stray males (all from Umatilla releases) were assigned to the subyearling program in an effort to reduce the impact these fish would have when they return. Usually, strays that have wire tags are not used in broodstock. To increase the effect of progeny returning from the natural $x$ natural and natural x Snake R. Hatchery crosses, those progeny were primarily assigned to our yearling program.

Table 6. Origins of fall Chinook and mating crosses contributing eggs to LSRCP Program, 2006.

| ORIGIN ${ }^{\text {a }}$ | REARING PROGRAM SLATED |  | PERCENT OF TOTAL PRODUCTION |
| :---: | :---: | :---: | :---: |
| LFH x LFH | 54.9\% | 75.4\% | 67.8\% |
| LFH x unknown | 0.3\% | 1.9\% | 1.3\% |
| Natural x Natural or Snake R. Hatchery | 39.6\% | 6.5\% | 18.8\% |
| Natural x stray or unknown | 5.2\% | 4.6\% | 4.8\% |
| Stray x stray or unknown | 0.0\% | 2.7\% | 1.7\% |
| Stray x LF H | 0.0\% | 8.9\% | 5.6\% |
| Totals | 100.0\% | 100.0\% | 100.0\% |

${ }^{\text {a }}$ LFH--Lyons Ferry coded-wire tag, unknown--unmarked/untagged fish with unresolved origins, Snake River Hatchery--scale analysis indicated these fish originated from Snake River Hatchery releases, stray--fish from out-ofbasin hatchery releases based on wire tag or scale analysis.

Historical information regarding eggtake, early life stage survival (Table 7), and marking and transfer numbers (Table 8) is provided. The decision to transfer 127,564-eyed eggs to IPC was made after the eggs from week four had been picked and mixed. The parental origins of the transferred eggs were representative of the take for the entire week: $75.8 \%$ of the eggs were from LFH x LFH origin matings, $12.4 \%$ from LFH x natural origin matings, $2.6 \%$ from entirely natural matings and $9.3 \%$ from matings in which at least one of the parents was a stray.

Rearing followed standard hatchery procedures that are available upon request. Detailed information regarding type and size of vessels used for rearing can be found in Lyons Ferry Hatchery Annual Reports. Marking was consistent with United States v. Oregon recommendations as listed in Appendix C.

${ }^{\text {a }}$ Eggs from ELISA positive females were incorporated into the rest of the brood stock in 1996-1998 and 20032004.
${ }^{\mathrm{b}}$ The destination of shipped eggs prior to 2003 can be found in previous Annual Reports. In 2005, eyed eggs were shipped to Oxbow Hatchery $(210,000)$, Umatilla Hatchery $(940,000)$ and NPTH $(30,000)$. In 2006, eyed eggs were shipped to Oxbow Hatchery.
${ }^{\text {c }}$ An additional 154,100 "eyed-eggs" were destroyed as ponded fry in February 2006. These eggs were from matings that included one stray parent.

## Juvenile Releases and Migration

Data regarding fall Chinook produced at LFH and released exclusively by WDFW are included in this section. Historical releases by WDFW, NPT, IDFG, and NOAA are presented in Appendix D.

## 2005 Brood Year

## Subyearling Release

Subyearlings were released at LFH and two additional sites upstream of LGR Dam in 2006. Prior to transport and release, juveniles from each release group were sampled at LFH to collect size and condition data as well as to evaluate tag loss for marked groups. Some of the fish were PIT tagged to allow collection of migration data through the Snake and Columbia Rivers.

The on-station release of 202,211 subyearlings (2005 broodyear) from LFH occurred at 6:00 pm on 1 June 2006. Fish were sampled on 31 May. Mean fork length was 90.4 mm (SD 9.8) and mean weight was 9.6 g (SD 2.9) or 47.2 fish per pound (fpp). The CV for fork length was 10.8 and condition factor ( K ) was 1.25 . Included in the release were 1,500 PIT tagged fish representing general production, and 10,581 fish PIT tagged as part of the COE transportation study. At the time of release, Snake River flow and spill recorded at Lower Monumental Dam was 115.1 kcfs and 19.9 kcfs respectively. The river was muddy and the mean daily water temperature at Lower Monumental Dam was $13.3^{\circ} \mathrm{C}$.

On 4 April 2006, an estimated 71,000 fry ( 181 fpp ) were accidentally released into the Snake River from LFH when a seal along the screen at the bottom of the raceway failed. These fish were originally slated for the yearling program (2007 release). Fry in the subyearling program were used to make up for the loss.

## Snake River near Couse Creek

Two groups of BY05 subyearlings were released into the Snake River near Couse Creek Boat Launch (Rkm 253.7). Both groups were marked/tagged with an adipose fin clip and CWT. The first release was part of a study to compare acclimated fish (released from the Captain John acclimation site) to those released directly into the river. The second release should not be used in comparisons between direct and acclimated groups because they were released at a different date than the acclimated fish.

The first group of fish $(200,820)$ was released on 30 May and were 55.6 fpp, estimated using pound counts at release. A week prior to release the fish were sampled to determine individual lengths, weights, and K-factors, and to implant 3,484 PIT tags. Mean fork length was 85.7 mm (SD 7.4) and mean weight was 7.6 g (SD 2.2) or 60.0 fpp . The CV for fork length was 8.7 and K was 1.11. An additional 12,081 fish from this group were PIT tagged for the COE transportation study.

The second group ( 211,508 fish at 50.0 fpp ; estimated using pound counts at release.) was released on 22 June. The release number includes 10,874 fish that were PIT tagged for the COE
transportation study. Mean fork length was $93.6 \mathrm{~mm}(\mathrm{n}=340$, SD 8.7) and mean weight was 9.4 g (SD 2.5) or 48.4 fpp . The CV for fork length was 9.3 and K was 1.11 . Fish were sampled on 20 June.

At the time of the releases mean daily Snake River flow and spill recorded at LGR Dam were 116.0 kcfs and 41.2 kcfs for the May release, and 64.5 kcfs and 20.0 kcfs for the June release. Mean daily flow and spill recorded at Lower Monumental Dam for the early release was 116.3 kcfs and 36.8 kcfs , and 65.7 kcfs and 17.3 kcfs for the latter.

## Grande Ronde

Two groups of 2005 broodyear subyearlings were released into the Grande Ronde River near the mouth of Cougar Creek from 19-21 June 2006. One group (200,432 fish at 50.7 fpp ; estimated using pound counts at release) was marked/tagged with an adipose fin clip and CWT. An associated group of 208,733 unmarked/untagged fish at 50.1 fpp (estimated size from pound counts at release) was released concurrently. Pre-liberation sampling was conducted at LFH on 16 June to gather individual fork lengths, weights, and K-factors. Mean fork length was 92.7 mm (SD 7.4) and mean weight was 9.2 g (SD 2.3) or 49.3 fpp . The CV for fork length was 7.9 and K was 1.13. During the Grande Ronde release, the daily average Snake River flow recorded at LGR Dam ranged 67.5-79.7 kcfs and daily average spill ranged 20.2-20.3 kcfs. Daily average flow and spill recorded at Lower Monumental Dam ranged 66.6-78.13 kcfs and 17.2-23.6 kcfs, respectively.

## Yearling Release

We released 503,160 yearling fall Chinook (BY 2005) into the Snake River at LFH between 2-6 April 2007. Two groups of fish were coded-wire-tagged and marked with a red VIE tag behind the left eye. One half of the group was adipose fin-clipped (CWT: 63-35-98) and the other half was not adipose clipped (CWT: 63-35-97). A power outage during tagging resulted in a small group of 1,500 fish having an adipose clip as the only mark. These ad-clipped fish were combined with 48,648 unmarked/untagged fish (surplus from other production groups), and added to the on-station release group in February 2007. Throughout the release, small groups of fish were removed and held in an adjacent raceway for sampling on April 3-6. Mean fork length for all days combined was 159.0 mm (SD 12.1) and mean weight was 42.4 g (SD 10.0) or 10.7 fpp. The CV for fork length was 7.6 and K was 1.04 . More specifically, for the Ad+CWT+VIE group, mean fork length was $157.4 \mathrm{~mm}(\mathrm{SD} 10.7)$ and CV of length was 6.8. The mean weight was 41.1 g (SD 8.9), or 11.0 fpp . The CWT+VIE group had a mean fork length of 161.9 mm (SD 12.8) with a CV of 7.9. The mean weight was 45.1 g (SD 11.5), or 10.1 fpp . During the release, average daily Snake River flow recorded at Lower Monumental Dam ranged from 32.659.3 kcfs and the spill ranged from 0.0-23.3 kcfs.

## Survival Rates to Release

We used the estimated number of eggs and fish present at life stages in the hatchery for 19902005 broods to calculate survival rates within the hatchery environment (Table 9). Survivals are based on an estimated number of green eggs, calculated by subtracting green egg equivalents of eggs/fry not retained for LFH rearing (IPC, NPTH, culled strays) from the total eggtake. For example, the hatchery reported the total number of green eggs taken and how many eyed eggs and fry are shipped or culled. Loss was estimated for green to eyed stage for the whole group, prior to shipping or culling. The number of eyed eggs shipped/culled was then converted into green egg equivalents and subtracted from the total green eggs taken. The resulting estimated number of green eggs was used in the actual life stage survival percentage calculations through release. Survivals for subyearlings and yearlings are the same through ponding because fry are not assigned to yearling or subyearling programs until that time.

Table 9. Estimated survivals (\%) between various life stages at LFH for fall Chinook of LFH/Snake River hatchery origin, 1990-2005 brood years.

| Brood year | Release stage | Green egg-ponded fry | Ponded fryrelease | Green egg-release |
| :---: | :---: | :---: | :---: | :---: |
| 1990 | Yearling | $86.8{ }^{\text {a }}$ | 94.5 | 82.1 |

## Adult Salmon Surveys

## Fall Chinook Redd Surveys

SRL personnel have conducted adult salmon surveys on the lower Tucannon River since 1985 (Appendix E). Survey sections generally covered the river from Rkm 1.1 to Rkm 29.0. The first 1.1 kilometers of the Tucannon River are deep slack water from the Snake River's Lower Monumental Dam reservoir and no surveys or estimates are made in that area: the habitat is poor and we presume no spawning occurs there. During 2006, landowner access restrictions prevented the surveying of 1.4 kilometers of river above the Starbuck Bridge within survey section 6 and 0.1 kilometers of river below the Starbuck Bridge within section 5. River conditions for viewing were good throughout the spawning season with low flows and clear water and we were able to survey $91 \%$ of the historical spawning area of fall Chinook.

## Escapement and Composition

We estimated 449 fall Chinook and 11 summer Chinook escaped to the Tucannon River in 2006. The total Chinook (fall and summer) escapement of 460 to the Tucannon River is based on an expansion factor of three fish per redd (Table 10). Since summer Chinook and fall Chinook build redds in the same sections of the river at similar times we were unable to determine which redds were associated with summer Chinook. Based on the recovery of one spawned out summer Chinook ( $2.3 \%$ of the Chinook recovered), we assumed that at least one redd was from a summer Chinook. We differentiate summer Chinook from fall Chinook based on the recovery of coded-wire-tags.

We believe using three fish per redd as an expansion factor provides a conservative estimate of fish spawning in the Tucannon River. Other methods have been used to estimate adults per redd upstream of LGR based on estimates of adult salmon above the Dam and redd counts from the Clearwater, Snake, Imnaha, Salmon, and Grande Ronde Rivers (Garcia et al. 2005). Garcia estimated 4.7 adults per redd ( 10 year average). Groves has estimated 3.1 adults per redd since 1993 (Phil Groves, IPC personal communication), using adjustments for over counts of fall Chinook at LGR and pre-spawning mortality estimates from a radio telemetry study on the Snake River (Mendel et al. 1993).

Table 10. Estimated escapement, \% stray component in carcasses sampled, and number of redds, and resulting estimates of smolts/redd and total number of migrants from Chinook spawning in the Tucannon River, 2002-2006.

| Year | Escapement |  | Redd Construction |  |  | Success of Spawning |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Estimated escapement ${ }^{\text {a }}$ | \% Strays in carcasses sampled | \# Redds observed | \# Redds in no access areas (estim) | Total \# of Redds (estim) | Estimated smolts/redd ${ }^{\text {b }}$ | Total Estimated \# emigrants ${ }^{\text {c }}$ |
| 2002 | 630 | $35.1{ }^{\text {d }}$ | 183 | 27 | 210 | 81 | 17,030 |
| $2003{ }^{\text {e }}$ | 474 | $65.8{ }^{\text {d }}$ | 143 | 15 | 158 | 452 | 71,465 |
| 2004 | 345 | $29.4{ }^{\text {d }}$ | 111 | 4 | 115 | 632 | 72,705 |
| 2005 | 205 | 60.0 | 61 | 7 | 68 | 307 | 20,971 |
| $2006{ }^{\text {f }}$ | 460 | 9.7 | 127 | 26 | 153 | pending | pending |

${ }^{\text {a }}$ This estimate was derived using three fish per redd.
${ }^{\mathrm{b}}$ This estimate was derived using redds counted above the smolt trap and estimates of emigration the following spring.
${ }^{c}$ This estimate was derived using the smolt per redd estimate above the trap and applying it to the total number of redds in the Tucannon River.
${ }^{\mathrm{d}}$ Minimum estimate.
${ }^{\mathrm{e}}$ Fish in excess of broodstock needs were returned to the Snake River, possibly affecting the magnitude of the run to the Tucannon River.
${ }^{f}$ We estimate $2.3 \%$ of the escapement were summer Chinook, based on recovery of one carcass.

In 2006, we collected forty-seven carcasses (Table 11). We collected heads and scales from each carcass and used CWT and scale analysis to determine the age and origin. The composition of the fall Chinook carcasses is listed in Tables 12 and 13, and Appendix F.

Fish with out-of-basin hatchery scale patterns were assigned to the Snake R. hatchery group because CWT recoveries shed doubt on the magnitude of the estimated out-of-basin return using scale determinations. This is a change in methodology from past years when these fish would have been called out-of-basin strays (Milks et al. 2007). Although the Tucannon River is a small, generally accessible river, carcass recovery is hampered by river topography, and predation. Therefore, estimates based on collected carcasses may not accurately represent the stock composition of fish in the River.

Table 11. Date and number of redds and carcasses counted on the Tucannon River in 2006.

|  | Chinook |  | Coho |  |
| :---: | :---: | :---: | :---: | :---: |

${ }^{a}$ One carcass was a summer Chinook.

## Reservoir Rearing

Scale analysis indicated that $30.8 \%$ of the Snake River natural origin fish recovered had reared in a Snake River reservoir their first year. We have documented that Snake River hatchery fish are reservoir rearing, but we do not know to what extent because scales have not been collected on wire tagged fish. Conner et al. (2002) suggested that dam construction in the Snake River basin might have altered juvenile fall Chinook salmon life history. Fall Chinook in the Snake River basin currently exhibit two life history types, namely ocean-type and reservoir-type (Connor et al. 2005).

Table 12. Age structure (total age), rearing history and origin of Chinook carcasses sampled on the Tucannon River, 2006.

## Coho

Although we observed no coho actively building redds, we suspected four digs were coho redds ( 6 redds when expanded for areas not surveyed). We recovered three coho carcasses, but none were female. Scale readings indicated two were hatchery 3-year-old fish and one was a hatchery jack. One of the 3 -year olds had a CWT verifying a Clearwater River release. We estimate the coho run to the Tucannon at 18 fish, using a 3 fish/redd calculation.

## Juvenile Salmon Emigration

## Subyearling Chinook

Juvenile fall Chinook were observed at the smolt trap (Rkm 3.0) from 1 February through 30 June 2006 when the trap was pulled for the season (Gallinat and Ross 2007). Median passage date for fall Chinook at the trap was 27 May. Fish ranged 35-108 mm in length.

We captured 3,073 Chinook, and estimate that $16,364(12,828-22,412)$ naturally produced Chinook smolts passed the Tucannon River smolt trap during 2006. Based on the 53 redds estimated above the smolt trap during 2005 we calculated the number of smolts produced per redd was 307. Including estimated juvenile production from below the smolt trap, we estimate that 20,971 naturally produced Chinook smolts left the Tucannon during 2006.

The egg-to-smolt survival of fall Chinook downstream of the smolt trap may be less than above the trap because the river slows, increasing the chance for sediment deposition to smother eggs in the gravel. No data are currently available to determine if such a differential exists for any production year. Because of these concerns, we suggest that production estimates be used cautiously.

## Coho

Juvenile coho salmon were incidentally captured at the smolt trap. This was the second year mark-recapture trap efficiency estimates were done for coho to determine if their recapture rates are similar to fall Chinook (Table 14). We trapped 406 coho in the smolt trap, and estimate that $1,510(991-2,449)$ naturally produced coho passed our smolt trap in 2006. Emigration numbers were only large enough to estimate recapture efficiency for three weeks during the 2006 emigration, so the estimate should be used cautiously.

Juvenile coho were observed at the smolt trap from 8 March through 30 June, the last day of trapping. The median abundance passage date at the smolt trap was 19 May. Fish ranged from $33-170 \mathrm{~mm}$ in length. Two age classes were observed with the majority of the fish being subyearlings. Based on a histogram of fork length data, subyearlings were $33-90 \mathrm{~mm}$ and yearlings were larger than 90 mm . We did not observe any fish exhibiting the morphology of a Chinook x coho hybrid.

Table 14. Trapping efficiency estimates for fall Chinook and Coho at smolt trap on the Tucannon River, 2007.

| Week ending | Fall Chinook <br> Recapture efficiency | Coho <br> Recapture efficiency |
| :--- | :---: | :---: |
| 21 May | 14.8 | unknown |
| 28 May | 17.5 | 29.0 |
| 04 June | 33.7 | 25.9 |
| 11 June | 31.5 | 15.8 |
| 19 June | 17.2 | unknown |
| 26 June | 29.6 | unknown |

## Summary of Fall Chinook Run Size and Composition

## Return to LFH

Fish trapped at LFH that were processed (killed) during fall Chinook spawning are listed in Appendix G. Two of the fish processed were minijacks ( $<30 \mathrm{~cm}$ ). We estimate that 14 of the fish (jacks) listed as trapped at LFH were actually fish trapped at LGR Dam. All fish returned to the Snake River were excluded from the LFH run composition, since they may be included in Tucannon River recoveries or the LGR run composition.

The composition presented in Table 15 is based on data from the fish trapped and processed at LFH (Appendix G). Because not all trapped fish were retained for broodstock, the table may not accurately reflect escapement to LFH or the Snake River run at large. Both Umatilla and Klickitat hatcheries released fish that were identically marked (blank wire tag only). The BLANK wire tag recoveries that were aged indicate that group of fish was either age 3 or age 5 . We do not know the origin of the age 3 fish because neither Umatilla nor Klickitat hatchery released BLANK wire tagged fish that year. The age 5 fish are not associated with any CWTs that we recovered. Klickitat Hatchery did release a group of BLANK wire tagged fish from BY00, but those fish were not associated with any CWTs. Although we are unable to determine the release location of the BLANK wire tagged fish, we can identify them as out-of-basin strays.

Table 15. Composition of Chinook trapped and processed (killed) at LFH during 2006.

| Origin | Adults | Jacks | Comp of Adults | Comp of <br> Jacks |
| :--- | :---: | :---: | :---: | :---: |
| LFH/Snake River Hatchery |  |  |  |  |

| Strays (out-of-basin) | 6 | 1 | $0.4 \%$ | $0.2 \%$ |
| Hatchery origin (unassigned) | 56 | 1 | $3.6 \%$ | $0.2 \%$ |
| Unknown origin (natural or hatchery) | 11 | 4 | $0.7 \%$ | $0.9 \%$ |
| Spring or Summer Chinook | 2 | 0 | $0.1 \%$ | $0.0 \%$ |
| Totals | 13 | 0 | $0.8 \%$ | $0.0 \%$ |

${ }^{\text {a }}$ Includes fish from LSRCP, NPTH, and IPC programs.

## Returns to LGR Dam and Composition of Fish Hauled to LFH from LGR Dam

The run reconstruction to LGR Dam, with bounds around the data, is presented in Appendix H. We thank the Pacific Salmon Commission Southern Fund for funding this project.

Chinook were counted 24 hours per day during August, 16 hours per day September through October, and 10 hours per day from November through 15 December at the counting window (U.S. Army Corps of Engineers, 2006). Window counts estimated 8,048 adults and 6,721 jacks
reached LGR Dam in 2006 (Figure 5). The Chinook passing LGR Dam after 17 August are designated as falls based on arrival date, which is inaccurate because of the overlap between the fall and summer Chinook runs. In addition, fish counts at the dams do not adjust for fish that crossed the dam and fell back through the juvenile bypass system (fallback event) or fish that recrossed the dam after a fallback event (double counting).

Figure 5. Fall Chinook window counts at LGR Dam, 1976-2006.

Fallbacks were documented from August-December at the juvenile smolt bypass facility, downstream of LGR (Fred Mensik, WDFW, and Mike Halter, COE, personal communication). Fish moving downstream through the LGR Dam forebay that encounter the submersible traveling screens are diverted downstream through the juvenile bypass system and move across a separator. The system separates adults from juveniles to allow adults to be diverted back to the river.

Based on data collected at the LGR juvenile bypass facility, we estimate a total of 845 fallback events occurred at LGR Dam during 2006. Fallback events documented at the juvenile facility during the month of August were not included since data were not recorded regarding run of Chinook encountered (summer Chinook may have been included).

Of the Chinook captured and scanned for wire during juvenile sampling at LGR Dam (Table 16), $97.2 \%$ of the jacks were of hatchery origin. The majority ( $82.5 \%$ ) of the jacks sampled had a left red elastomer tag indicating they originated from yearling releases downstream of LGR at LFH. Since scales were not taken on the unmarked/untagged group we cannot determine their origin, although we suspect they are hatchery fish.

Table 16. Documented fallbacks of fall Chinook at the LGR juvenile bypass facility.

| Sampling protocol and marks | Estimated number of jack fallbacks at Juvenile collection facility | Estimated number of Adult fallbacks at separator | Estimated number of Jack fallbacks at separator |
| :---: | :---: | :---: | :---: |
| scanned for wire: |  |  |  |
| ADCWTLR | 173 |  |  |
| CWTLR | 175 |  |  |
| ADLR | 5 |  |  |
| LR only | 6 |  |  |
| Adwire | 29 |  |  |
| wire only | - 30 |  |  |
| AD only | 5 |  |  |
| unm/untag/noVI | I 12 |  |  |
| not scanned for wire: |  |  |  |
| ADLR |  | 48 | 17 |
| AD only |  | 114 | 54 |
| LR only |  | 17 | 21 |
| unm/noVI |  | 84 | 54 |
| Total | 435 | 263 | 147 |

The adults and jacks encountered at the separator were examined for size, fin clips, VIE, and operculum punches. We estimate that at least $68.1 \%$ of the adults sampled at the separator were of hatchery origin based solely on adipose clips and VIEs, but expect the rate is actually much higher. The use of adipose fin clips as a primary indicator of hatchery origin is no longer a reliable method since many hatchery fish are being released into the Snake River basin without an adipose fin clip. We estimate that at least $63.0 \%$ of the jacks collected at the separator were of hatchery origin but the estimate may be as high as $89.4 \%$ if the composition of unclipped jacks without VIEs was similar to jacks sampled at the juvenile facility.

Fish hauled from LGR to LFH that were processed (killed) are listed in Appendix G and Table 17. We did not process any minijacks from LGR although one minijack was released at the LGR trap. This would expand to approximately seven minijacks during the trapping period. Additional fish trapped at LGR that were hauled to Nez Perce Tribal Hatchery (NPTH) and specific data about those fish will be included in an upcoming NPT Annual Report (Bill Arnsberg, NPT, personal communication). An estimate of the composition of the fall Chinook run to LGR will require the addition of NPT data to what is presented in this report.

Table 17. Fish trapped at LGR Dam, hauled to LFH, and processed (killed) to determine composition, 2006.

| Origin | Adults | Jacks | \% of Adults | \% of Jacks |
| :--- | :---: | :---: | :---: | :---: |

| Totals | $\mathbf{6 8 0}$ | $\mathbf{4 2 6}$ | $\mathbf{1 0 0 . 0}$ | $\mathbf{1 0 0 . 0}$ |

## Recoveries of Wire Tagged LFH/Snake River Hatchery Fall Chinook Outside of the Snake River

To document where recoveries of LFH/Snake River hatchery fall Chinook occurred in 2006, we queried the Regional Mark Information System (RMIS) database on 19 May 2008 for all tag recoveries (all tag statuses) of WDFW released LSRCP fall Chinook (Appendix J). Releases of Snake River hatchery fish by the NPT (LSRCP and NPTH programs) and fish associated with the IPC program were not included. Coded-wire tag recoveries were grouped by freshwater and saltwater, then by state, then by recovery site. The freshwater and marine determinations were based upon the RMIS recovery location codes. We report recoveries at hatchery racks, fish traps, and from carcass surveys to show the final locations of fish that strayed or were intercepted outside of the Snake River basin. The remaining fishery recoveries were grouped together. Besides informing managers about the geographic location of harvested or intercepted fall Chinook, these data were the basis for expanded estimates of the contribution of LSRCP fall Chinook to out of Snake R. Basin fisheries (see Status of Achieving Mitigation).

## Smolt-to-Adult Return Estimates

Appendix K lists smolt-to-adult return (SAR) estimates from our yearling and subyearling production groups grouped by fin clip, (BY99 through BY05), for return years through 2007. These data were derived from recoveries from RMIS and include Snake River run reconstruction estimates of live fish that were wire tagged. Neither dataset was expanded for tag loss, sample detection method, or fishery. When comparing SARs it is important to compare groups based on fin clip, because some ocean fisheries only visually sample fish for fin clips (indicator of presence of a CWT) while others sample every fish electronically regardless of clip. These discrepancies will result in an underestimation of harvest by ocean fisheries for unclipped CWT subyearlings.

Yearling releases (Table 18) continue to provide a survival advantage over subyearling releases (Table 19) although it is highly variable among years. We also present data showing a survival advantage of onstation subyearlings when compared to direct releases into the Snake River near Couse Creek and the Grande Ronde River, although it is based on incomplete broodyear returns.

Table 18. Average percent smolt-to-adult return rates to the Snake River for yearling fall Chinook released by WDFW.

${ }^{\text {a }}$ Fish barged below Bonneville Dam received head injuries when they were loaded on the barge. There was some immediate mortality when they were loaded, but once the flow was reduced the injuries decreased.

## Status of Achieving Mitigation

The long-range goal is to return 32,700 fall Chinook to the Snake River basin, including 18,300 hatchery fish. Furthermore, the long-range harvest goal was 98,100 fall Chinook taken in commercial fisheries and 32,700 fall Chinook taken in sport fisheries (U.S. Army Corps of Engineers 1975) in the Columbia River system and the Ocean. In past reports, the harvest component of mitigation has been overlooked and recoveries of CWTs as downloaded from RMIS have not been expanded to reflect the take of non-CWT fish and non-clipped fish. The following methods of adjusting harvest data are preliminary and are our first attempt to account for the total number of Washington's LSRCP mitigation fish that were taken in fisheries. The data presented below are only for fall Chinook released by WDFW that are part of the LSRCP mitigation (Table 20). The adult returns from NPT released fish from LSRCP acclimation sites above LGR Dam are not presented in this report.

|  | Grand Total |  | 7,885 |
| ${ }^{a}$ Harvest estimates have been adjusted to account for sample detection method, fishery, tagloss, and are fully expanded to reflect total take and escapement of tagged, untagged, AD clipped, and non-fin clipped fall Chinook released by WDFW. Adults are combined with jacks in this table. <br> ${ }^{\mathrm{b}}$ Included in the Snake River estimate are estimates of fall Chinook spawning in the Tucannon River, fall Chinook trapped at LFH and used for broodstock, and the run of fall Chinook to LGR Dam. |  |  |  |

## Harvest Adjustments for Non-Selective Fisheries

Non-selective fisheries retain any fall Chinook captured. Non-selective fisheries include all the commercial and tribal net fisheries. Canada and Alaska sport fisheries are also non-selective. The RMIS database was used to generate estimated (ESTD) harvest data of CWT tagged fish. Fish without CWTs are not reported to RMIS and therefore the harvest estimates must be expanded to reflect total take for mitigation purposes. Adjustments to RMIS harvest data were done differently based upon CWT detection methods listed below.

## Visual Detection Method

Visual detection means only adipose fin clipped fish were scanned for wire. Since Canada and Alaska only sample adipose clipped fish but allow take of all fish, we expanded the RMIS estimated recoveries (ESTD) by determining an expansion factor based on release data of each tag code recovered. For example if the tag code recovered was from a release of fish that had ADCWT, CWT only, AD only, and unmarked/untagged fish in the release, we used the following formula to expand harvest data of CWT fish to represent the total take:

ESTD CWTs harvested by fisheries from RMIS x (total \# released from that tagcode/ \# ADCWT in the release) = ESTD total take

## Electronic Detection Method

Electronic detection method scans all fish for wire regardless of fin clip. For this detection type we used the following formula to expand the harvest data of CWT fish to estimate the total take:

ESTD CWTs harvested by fisheries from RMIS x (total \# released represented by that tagcode/ (\# ADCWT in the release + \# CWT in the release) $=$ ESTD total take

## Discrepancies Between Detection Methods Reported to RMIS

We found discrepancies in the RMIS data when looking at recoveries of two broodyears of yearling fall Chinook that were index tagged. The data showed that the Tribal gillnet fishery in the Columbia River was sampled using electronic detection. If that were the case we would reasonably expect the numbers of recoveries from the ADCWT fish to be similar to the numbers of recoveries from the non-clipped CWT fish. In both broodyears where there were indexed tagging groups, there were no recoveries from the non-clipped CWT fish. Moreover, at LFH we electronically sample all fish. If the harvest of the AD clipped and no-clip groups occurred differentially, we would expect that recoveries at LFH would reflect those differences; that did not occur. Recoveries from both groups were nearly equal, therefore we presume that the harvest data submitted to RMIS should have indicated visual, not electronic detection type. If electronic detection was used, not only would the expansion rate be less, but also no adjustment would have been made for the lack of recoveries from the non-clipped CWT groups, thus underestimating the LSRCP component.

We adjusted the Columbia River Tribal Gillnet fisheries ESTD harvest of ADCWT groups by applying the formula for visual detections to estimate the total harvest of each tag code. To estimate the total take of non-clipped CWT groups of a different tag code, but from the same broodyear, we used the smolt-to-adult recovery rate of the ADCWT group as surrogates and applied that to the total number of fish released.

## Harvest Adjustments for Mark Selective Fisheries

To adjust ESTD harvest of ADCWT groups to reflect the total take in AD selective fisheries we had to account for fish released with an AD clip that were not wire tagged. The Columbia River sport fisheries are mark selective and were expanded using the following formula:

ESTD CWTs harvested by fisheries from RMIS x (total \# AD + total \# non-clipped fish released from that tag code/ \# ADCWT) = ESTD total take

## Fall Chinook Run to Lower Granite Dam in 2004

The run reconstruction to LGR was completed 01 May 2009 and is included in Appendix L. Fish were trapped at two trapping rates throughout the season. To distinguish which fish were trapped at each rate, PIT tags were implanted in adults retained for broodstock and for run reconstruction purposes. Unfortunately due to tag loss, there were many fish whose trapping rates had to be estimated. We recommend that PIT tags not be used for this purpose in the future.

## Conclusions and Recommendations

The fall Chinook program at LFH requires substantial coordination. The program is currently being managed to meet the requests of Tribal, state, and federal co-managers. Conclusions and recommendations listed below are not in priority order.

1. Hauling excess fish back to the Snake River at the end of the season will continue to occur which will affect run timing and spawning area selection.

Recommendation: Mark all fish released from the hatchery to allow accounting of them post-release. This will allow us to document the relationship between trapping location, release location, and last noted detection area.
2. The sizes of the adult ponds at LFH limit our flexibility when working fish during spawning. The holding ponds are very large and more fish can be held in the ponds than can be crowded into the fallback channel. Over-crowding fish in the fallback channel causes undue stress, which can lead to pre-spawning mortality. The vessels cannot be divided with crowders because each pond needs to be drained all at once. Also, an open pond must be available for use when fish are returned back to the pond. Since there are only two ponds slated for fish trapped from each location (LFH and LGR), one must be completely emptied before fish can be returned to that pond. In addition, fish that were previously inoculated must be kept separate from new arrivals. Differences in run composition and spawn timing between fish trapped at each location exacerbate the situation. Dividing the ponds would enable us to spawn one pond of LFH trapped fish and one pond of LGR trapped fish on the same day. This would allow us to work within our spawning protocol, and decrease the number of males used multiple times (maximize $\mathrm{N}_{\mathrm{b}}$.

Recommendation: Divide the adult holding ponds lengthwise to give us more flexibility when processing adults at spawning.
3. Fallback at LGR Dam is known to occur. Data from a 1993 telemetry study indicated fish released as juveniles at LFH occasionally cross LGR Dam when they return as adults, then descend through the system to be trapped at LFH. Likewise, out-of-basin fish have exhibited similar migration patterns. Any fish trapped at LGR and released to continue upstream is operculum punched. However, we have not received complete fallback reporting from COE sampling at the juvenile bypass facility. This incomplete data provides an inaccurate assessment of fallback at the dam, affecting the accuracy of our run-reconstruction and the estimate of true escapement to above the dam.

Recommendation: Request the COE continue collecting data regarding fallback from fish encountered at the juvenile collection facility and separator located at LGR Dam. Data collected should include operculum punches and VIE color and location on nonjuvenile fall Chinook encountered so that we can adjust data used in run reconstruction estimates.

Recommendation: Continue to use fallback data from fish encountered at the juvenile collection facility in the run reconstruction estimates of fish passing LGR.
4. Estimated composition of the run to the Tucannon River may be biased. The sample size of carcasses recovered each year is very small, and the carcasses recovered may not adequately reflect the composition of fish spawning in the Tucannon. Run composition is estimated based on adults recovered. Since we recover more females than males it is possible we are overestimating the older age classes (females) and under estimating the younger age classes (males and jacks).

Recommendation: Increase carcass recovery efforts to increase the numbers of fish recovered.
5. The release of unmarked/untagged fish into the Snake River may be causing us to underestimate escapement of fish associated with LSRCP mitigation. The absence of CWTs in these fish forces us to depend upon scale analysis to differentiate in-basin (LSRCP or IPC) from out-of-basin fish.

Recommendation: Adipose clip and/or tag 100\% of the LSRCP releases so returns can be accurately estimated and naturally produced fish can be incorporated into broodstock with greater accuracy.

Recommendation: Begin thermal marking otoliths in all of the fall Chinook produced at LFH. By doing this we would be able to better determine stray rates of untagged fish. Even if our releases were not wire tagged or fin clipped, we would still be able to tell with $100 \%$ confidence if a fish were produced by our hatchery. It would take five years before all of the returning LFH hatchery fish would be marked. At that time any hatchery fish, as determined by scale pattern analysis, that did not have an otolith mark would be considered a stray.

Recommendation: Continue to collect scales on fish from CWT tagged releases in order to refine criteria used to determine origins of unmarked/untagged fish.

# Appendix C: United States v. Oregon Production and Marking Table 

Appendix C. Table B4 in Interim Management Agreement for Upriver Chinook, Sockeye, Steelhead, Coho, and White Sturgeon. Snake River fall Chinook production for Brood Years 2005-2007 for the Lower Snake River Compensation Program (LSRCP) at Lyons Ferry Hatchery, the Fall Chinook Acclimation Program (FCAP), the Idaho Power Program (IPC) and the Nez Perce Tribal Hatchery (NPTH)

| Production <br> Priority | Rearing <br> Facility | Release <br> Number | Release <br> Location | Life stage | Mark |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Tier One assumes rearing of 2.2 million subyearlings at Lyons Ferry Hatchery and | 1.0 million eggs for IPC program. ${ }^{\prime}$ |  |  |  |  |

Footnotes for Table B4:

1. Bonneville Power Administration directly or indirectly funds all programs except the IPC program.
2. IPC program may be implemented at IPC Oxbow Hatchery and/or other hatcheries, such as Umatilla Hatchery. Priority 5 production may be implemented at Oxbow Hatchery and, priorities 6, 7 and 10 production may be implemented at Umatilla Hatchery if broodstock shortage limits full implementation of Tier 1.
3. These would replace subyearlings released by IPC under priorities 5 and 7, and all IPC releases would occur at Hells Canyon Dam. These will be combined with the Priority \# 4 Big Canyon and Captain John marking groups for harvest evaluation.
4. Early spawning component of NPTH program.
5. Split into two release groups at two locations of 200 K each depending on final study design. If so, they will have appropriate tags and AD-clips for evaluation of the study.
6. The parties acknowledge that facilities improvements will be required to achieve all the releases in Tier 2.
7. For Broodstock collected at Lower Granite Dam, the parties will determine annually the broodstock collection protocol.

Appendix D. (continued) LFH/Snake River hatchery origin fall Chinook releases with number marked, tagged, and unmarked by release year, rearing strategy, Brood year and type of release.

| Release Year | $\mathbf{S} / \mathbf{Y}^{\mathrm{a}}$ | Brood Year | Release Location-Type | Release Date | Number of Fish Released ${ }^{\text {b }}$ |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | CWT <br> Code | AD+CWT | $\begin{aligned} & \hline \text { CWT } \\ & \text { Only } \end{aligned}$ | Ad-Clip Only | Unmarked Untagged | FPP | VIE <br> Mark | $\begin{gathered} \text { \% } \\ \text { VIE } \end{gathered}$ | Other |
| 2007 | Y | 2005 | CJ1-volitional | 13 April | 612506 | 69,180 | - | 112 | 9,911 | 10.0 |  |  | PIT 3,995 |
| 2007 | Y | 2005 | CJ1-volitional | 13 April | 612509 | - | 78,588 | - | 708 | 10.0 |  |  |  |

${ }^{\text {a }} \mathrm{S} / \mathrm{Y}$ indicates subyearling or yearling rearing strategy.
${ }^{\mathrm{b}}$ Numbers presented do not necessarily match hatchery records for fish per pound because of reporting constraints for the hatchery. Release information for some NPT release sites that had multiple CWT codes was estimated by WDFW based upon proportions of fish at tagging since those data were not available at the time this report was printed.

# Appendix E: Tucannon River Survey Sections 2006 and Historical Escapement Estimates 

Appendix E. Table 1. Description and length of sections, survey length, percent of reach surveyed, estimated total number of Chinook redds in the Tucannon River, 2006.

|  |  | Length of <br> section <br> (Rkm) | Length of <br> section <br> surveyed <br> (Rkm) | \% of <br> productive <br> reach <br> surveyed | Chinook <br> Estimated total \# <br> of Redds |
| :---: | :--- | :---: | :---: | :---: | :---: |
| 1 | Description | Mouth of Tucannon R. to hwy 261 Bridge | 2.8 | 1.7 | 100 |
| 2 | Highway 261 Bridge to smolt trap | 0.2 | 0.2 | 100 | 13 |
| 3 | Smolt trap to Powers Bridge | 0.5 | 0.5 | 100 | 1 |
| 4 | Powers Bridge to hog barns | 1.2 | 1.2 | 100 | 10 |
| 5 | ${\text { Hog barns to Starbuck Bridge }{ }^{\text {c }}}^{2}$ | 2.5 | 2.4 | 100 | 12 |
| 6 | Starbuck Bridge to Fletcher's Dam ${ }^{\text {d }}$ | 2.7 | 1.3 | 48 | 38 |
| 7 | Fletcher's Dam to Smith Hollow | 2.9 | 2.9 | 100 | 48 |
| 8 | Smith Hollow to Ducharme's Bridge | 4.4 | 4.4 | 100 | 10 |
| 9 | Ducharme's Bridge to Highway 12 Bridge | 5.5 | 5.5 | 100 | 18 |
| 10 | Highway 12 Bridge to Brines Rd. Bridge ${ }^{\text {e }}$ | 6.2 | 4.9 | 100 | 4 |

${ }^{\text {a }}$ Section lengths measured using Maptech, Terrain Navigator Pro version 6.0 software.
${ }^{\mathrm{b}}$ Percentage is based upon length of stream that is presumed to successfully produce fry.
${ }^{\text {c }}$ Decreased section length by 0.3 Rkm in 2005.
${ }^{\mathrm{d}}$ Increased section length by 0.3 Rkm in 2005.
${ }^{\mathrm{e}}$ Formerly Enrich Bridge.
${ }^{f}$ Includes an estimated 4 summer Chinook redds based on percent of Chinook carcasses that were summers.

Appendix E, Table 2. Estimated escapement, \% stray component of the run, and number of redds, and resulting estimates of smolts/redd and total number of migrants from fall Chinook spawning in the Tucannon River, 1985-2001.

|  | Escapement |  | Redd Construction |  |  | Success of Spawning |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Estimated escapement ${ }^{\text {a }}$ | \% Strays in fish sampled ${ }^{\text {b }}$ | \# Redds observed | \# Redds in no access areas (estim) | Total \# of Redds (estim) | Estimated smolts/redd ${ }^{\text {c }}$ | Total Estimated \# emigrants ${ }^{\text {d }}$ |
| $1985{ }^{\text {e }}$ | 0 | No sampling | 0 | No estim | 0 | unknown | unknown |
| $1986{ }^{\text {f }}$ | $2^{\text {g }}$ | No sampling | 0 | No estim | 0 | unknown | unknown |
| 1987 | 48 | 0 | 16 | 0 | 16 | unknown | unknown |
| 1988 | 78 | 0 | 26 | 0 | 26 | unknown | unknown |
| 1989 | 150 | 27.9 | 48 | 2 | 50 | unknown | unknown |
| 1990 | 186 | 30.8 | $62^{\text {h }}$ | 0 | 62 | unknown | unknown |
| 1991 | 150 | 20.0 | 50 | 0 | 50 | unknown | unknown |
| 1992 | 69 | 0 | 23 | 0 | 23 | unknown | unknown |
| 1993 | 84 | 6.3 | 28 | 0 | 28 | unknown | unknown |
| 1994 | 75 | 28.0 | 25 | 0 | 25 | unknown | unknown |
| 1995 | 87 | 33.3 | 29 | 0 | 29 | unknown | unknown |
| 1996 | 144 | 95.5 | 43 | 5 | 48 | $0.6{ }^{\text {i }}$ | 29 |
| 1997 | 93 | 5.3 | 27 | 4 | 31 | 712 | 22,076 |
| 1998 | 132 | 7.1 | 40 | 4 | 44 | 15 | 666 |
| 1999 | 87 | 9.1 | 21 | 8 | 29 | 441 | 12,799 |
| 2000 | 60 | 27.8 | 19 | 1 | 20 | 468 | 9,352 |
| 2001 | 219 | 14.9 | 65 | 8 | 73 | 336 | 24,545 |

${ }^{a}$ This estimate was derived using three fish per redd.
${ }^{\mathrm{b}}$ Minimum estimate.
c This estimate was derived using redds counted above the smolt trap and estimates of emigration the following spring. Estimates began in 1997 when the smolt trap was moved to its current position at Rkm 3.0, at an area low enough in the system to trap fall Chinook.
${ }^{d}$ This estimate was derived using the smolt per redd estimate above the trap and applying it to the total number of redds in the Tucannon River.
${ }^{\mathrm{e}}$ Based on one survey completed 12/17/85.
${ }^{f}$ Based on one survey completed 11/18/86.
${ }^{g}$ Two carcasses counted but not sampled.
${ }^{h}$ Correction of number of redds observed that was presented in the 1990 Annual Report.
${ }^{i}$ Flood event occurred January of 1997, nearly eliminating all the progeny from the 1996 spawn.

# Appendix F: Salmon Carcass Recoveries from, and Estimated Composition of Chinook to the Tucannon 

 River 2006(Origin states origin, brood year, age at release, and release site (LF01SCJA is a LFH hatchery origin fish from the 2001 brood year, released as a subyearling, from the Captain John Acclimation facility)).

Appendix F. Estimated composition and age of carcasses collected in the Tucannon River in 2006.

## I. Background

In Phase 1 of this study, we developed bootstrap confidence intervals for groups, including wild fish, of fall Chinook salmon, Oncorhynchus tshawytscha, returning to Lower Granite dam near Lewiston, ID and Clarkston, WA. This statistical analysis depended on 3 data sets-daily window counts at the dam, data collected from fish trapped at the dam, and data from fish processed at Lyons Ferry Hatchery or the Nez Perce Tribal Hatchery. The result was $90 \%$ confidence intervals for each group.

The window count data were used to estimate the numbers of adults and jacks arriving at the dam before and after the trap at the dam was operated. In this case, window counts supplied numbers from August $18^{\text {th }}$ to September 5 and from November $21^{\text {st }}$ to December $15^{\text {th }}$. The trap was run from September $6^{\text {th }}$ to November $20^{\text {th }}$. Since the trap was open $13 \%$ of the time, dividing the numbers of fish trapped by $13 \%$ provides an estimate of fish arriving at the dam for the trapping period. Data collected on trapped fish include sex, length, markings, presence or absence of coded wire tags and PIT tags, and approximately $66 \%$ of the untagged fish were scale sampled for age and origin determinations. Some trapped fish were released at the dam and the rest were transported to the hatcheries for processing. More observations were made at the hatcheries of sex, length, and markings and, in addition, coded wire tags were retrieved and read and PIT tags were read and recorded. Scales were collected on all untagged fish. The processing data were used to assign group origin (including wild) to each fish. Fish released at the dam during the trapping period were assigned origins from scale samples taken at the trap.

The group proportions were also applied to fish arriving before and after trapping with the exception of determining numbers of wild fish. Wild fish arrive at the dam earlier than hatchery fish in general (Figure 1). Expanding the wild fish proportions from the trapping period to preand post-trapping window counts would not accurately portray the run timing of wild fish.

The numbers of wild fish arriving during pre- and post-trapping was estimated by fitting an exponential regression to the $\%$ wild among unmarked fish during trapping and projecting the percentages to the weeks before and after trapping. The percent wild among unmarked fish was determined from scale samples taken from approximately 2 out of 3 trapped fish. Given these estimates of \% wild adults and jacks before and after trapping by week, the numbers of wild adults and jacks were found by multiplying the expanded window counts of unmarked adults and jacks by the percentage.

After subtracting the numbers of wild adults and jacks pre- and post-trapping, the group proportions were applied to the remaining fish to complete the overall run reconstruction. The result was an estimate of numbers of fish returning to Lower Granite dam by group. In 2005, the total number of fall Chinook returning was estimated to be 13985 with a $90 \%$ confidence interval of (13434, 14523).

The literature review reported in the Phase 1 report described various approaches to run reconstruction, but no other run reconstruction process was found that parallels this one. The detailed window count, trap, and processing data sets available for this study were unique as far as we can determine. In 2006, Flynn, Punt, and Hilborn published a paper in the Canadian

Journal of Fisheries and Aquatic Sciences describing a run reconstruction method for Bristol Bay sockeye. That paper described methods for estimating run timing more than run composition.

Figure 1. Regression of \% wild versus week for adults for 2005 (from Henry Yuen, USFWS).

## II. Validation of the bootstrap calculations

The run reconstruction process for the 2006 run was similar to the process used for the 2005 run with a few exceptions. The pre-trap period in 2006 ran from August $18^{\text {th }}$ to August $31^{\text {st }}$. The trap was run from September $1^{\text {st }}$ to November $21^{\text {st }}$. The post-trapping period was November $22^{\text {nd }}$ to December $15^{\text {th }}$. For 2006 we partitioned adults into female and male so 3 sex categories (F,M,Jack) were used. Additionally, we provide confidence intervals for aggregates of groups as well as individual groups.

Figure 2. Exponential decay regression of proportion wild among unmarked adults, 2006.

The regressions for unmarked fish for 2006 confirm that the proportion of wild fish among unclipped fish declines as the season progresses (Figures 2 and 3). The details of the regression calculations for percent of wild fish are detailed on the Wild trap tab of LGRfallchinook.xls. The two points in the upper right corner of the adult regression plot were proportions based on only 4 and 7 fish and were omitted from the regression. The numbers of estimated wild fish before the trapping period was 218 adults and 84 jacks. The numbers of estimated wild fish after the trapping period was 2 adults and 0.3 jacks. These numbers were relatively minor when compared to the total number of wild fish in the run (3744).

The inputs required to run the GAUSS program were:
Window counts-daily numbers of nonclipped and clipped adults and daily numbers of nonclipped and clipped jacks. Minijacks (fish $<30 \mathrm{~cm}$ ) were not counted at the window.

Trap data-date, week, sex, clip/noclip, coded wire tag presence or absence, PIT tag presence and number, and origin by scale sample. Note that the length of the fish was used to verify adult, jack, and minijack status, but was not read into the program. Minijacks were not included in the analysis.

Estimated Run Composition-numbers of females, males, and jacks for each group. Pre- and post-trapping composition combined with run estimate during trapping.

Figure 3. Exponential decay regression of proportion wild among unmarked jacks, 2006.

The bootstrap calculations as described in the Phase 1 report consisted of three parts. First a nonparametric bootstrap was applied to the window counts. This was done by fitting a model to the daily counts for adults and jacks, taking bootstrap samples of the residuals, and producing bootstrapped counts by adding the bootstrapped residuals to the daily model values. The model used is a 15 term fast Fourier transform (Figure 4). The bootstrapped daily counts were summed to obtain pre- and post-trapping estimates of numbers of adults and jacks arriving at the dam.

Second, a nonparametric bootstrap sample was taken from the trapping data base. In 2006, the number of fish trapped at the dam during the $13 \%$ trapping period was 1950. The estimate of numbers of fish arriving at the dam during the trapping period was $1950 / 0.13=15000$. The number of bootstrap samples taken from the trapping database was obtained by generating a
binomial random variable from a binomial with $n=15000$ and $p=0.13$. The average number of bootstrap samples taken was 1950 with a standard deviation of 41 .

Figure 4. Daily window counts and 15 term FFT model, 2006.

The bootstrap estimate of numbers of fish arriving at Lower Granite dam, $\mathrm{N}^{*}$, was the sum of the numbers of adults and jacks from the pre- and post-trapping bootstrap window counts and the number of bootstrap samples taken from the trapping database divided by 0.13 .

Third, the composition of the bootstrapped run was found by taking a parametric multinomial sample for each of the $\mathrm{N}^{*}$ fish. That is, we compute a multinomial trial $\mathrm{N}^{*}$ times where the probabilities of a fish having come from any group was the proportion of that group in the 2006 run. Thus each fish was assigned a group at random in proportion to the percentages of each group in the run. In any bootstrap cycle, the composition will vary, but in general will follow the multinomial probability law governed by the group percentages calculated for this year's run.

1000 bootstrap samples were generated. Given the original data, we had 1001 values for 1) numbers of fish arriving pre-trap, 2) numbers of fish arriving during trapping, 3) numbers of fish arriving post-trap, and 4) the numbers of each group returning. By adding the pre-trap, trap, and post-trap numbers, we also had 1001 values for total fish returning to Lower Granite. By ordering each sequence of 1001 numbers, we computed the $90 \%$ lower and upper confidence
interval for that quantity by locating the $5^{\text {th }}$ and $95^{\text {th }}$ quantile of the ordered list. For 2006, the values for numbers of fish returning appear in Table 1.

The confidence intervals for numbers returning overall and during trapping meet the goal of knowing the numbers of fish returning within $10 \%$ (the numbers in parentheses in Table 1 were $10 \%$ lower or higher than the estimates). The numbers of fish returning pre- and post- trapping were not known within $10 \%$. The pre-trapping confidence interval target was 526 to 642 . The calculated confidence interval of 475 to 695 was wider. The post-trapping confidence interval target was 73 to 89 . The calculated confidence interval was 27 to 142 . Because they only make up $4 \%$ of the total estimate, their imprecision does not greatly affect the precision of the overall estimator. This year's analysis shows that the bootstrap confidence intervals were valid and should be useful to the researcher and manager.

Table 1. Numbers of fall Chinook arriving at Lower Granite dam, 2006.

| Time period | Estimate | Lower CI (10\%) | Upper CI (10\%) |
| :--- | :---: | :---: | :---: |
| Pre-trapping | $\mathbf{5 8 4}$ | $475(526)$ | $695(642)$ |
| Trap period | $\mathbf{1 5 0 0 0}$ | $\mathbf{1 4 4 0 0}(13500)$ | $\mathbf{1 5 4 6 9}(16500)$ |
| Post-trapping | $\mathbf{8 1}$ | $27(73)$ | $142(89)$ |
| 2006 Season | $\mathbf{1 5 6 6 5}$ | $\mathbf{1 5 0 7 9}(14098)$ | $\mathbf{1 6 1 1 7}(17232)$ |

Finding confidence intervals for individual groups was a more challenging undertaking. The $200690 \%$ confidence intervals for groups appear in Table 2. There were 109 groups. Although the bootstrap algorithm produces confidence intervals for each group, the results were not as precise as desired. A few of the confidence interval endpoints were within 10 percent of the estimate. This implies that we know the true number for those groups within $10 \%$ with $90 \%$ confidence. Estimates whose confidence intervals were within $10 \%$ of the estimate were marked with an *. Those estimates whose confidence intervals were within $20 \%$ of the estimate were marked with an ${ }^{* *}$. Return groups with around 300 returns were generally known within $10 \%$. Return groups with around 100 returns were often known within $20 \%$. Smaller return groups were hard to estimate.

Table 2. $90 \%$ confidence intervals by group for numbers of fall Chinook to Lower Granite 2006.

While individual researchers are very interested in the returns for a particular group, managers are more likely to be interested in the bigger picture. We calculated confidence intervals for strays (out-of-basin), Snake River hatchery fish, and wild fish by age (Table 3). Confidence intervals for small numbers of fish were still imprecise. For example, the confidence interval for male out of basin subyearling age 3 fish is 24 to 43 . The desired limits would be 30 to 36 . For larger numbers of fish, the goal of knowing the true number of fish returning within $10 \%$ with a confidence of $90 \%$ was met. For example, for female Snake River hatchery subyearlings of age 3 , the confidence interval was 319 to 382 . The desired limits were 316 to 386 . We were $90 \%$ confident that the true number of age 3 female Snake River hatchery subyearlings was within $10 \%$ of the estimate of 351 .

Table 3. $90 \%$ intervals for groups collapsed into stray, Snake River hatchery, and wild, 2006.

## III. "What if" analysis and the program

Having verified that the GAUSS program was stable and robust by applying it to a second year's data, we next ask if it was flexible enough to ask interesting questions about choices that can be made about counting, trapping, and processing. Since one can build any 3 data sets for the program as described above (window counts, trap data, and composition), any return and sampling protocol can be simulated easily.

For example, suppose the run was twice the size it was in 2005 or 2006. By combining all of the window counts for 2005 and 2006 and combining the trapping databases, we simulated a run that was the size of both years combined. Assuming the female/male ratios were the same for both years and the combined composition resembles the 2006 composition, we adopted the composition from 2006 for the composition data set. All of the estimates were within $10 \%$ of the truth with $90 \%$ confidence except for out-of-basin males and jacks (Table 4). For out-of-basin males the target confidence interval was 154 to 188 . The calculated confidence interval was 149 to 194 , slightly larger. For jacks the target confidence interval was 149 to 183. The calculated confidence interval was 144 to 184 .

Table 4. 90\% confidence intervals on combined data sets from 2005 and 2006.

| GROUP | lower | Female | Upper | Iower | Male | upper | lower | Jack | upper |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| OUT OF | 328 | 362 | 394 | 149 | 171 | 194 | 144 | 166 | 185 |
| BASIN |  |  |  |  |  |  |  |  |  |
| SNAKE R. | 4061 | 4212 | 4346 | 6295 | 6506 | 6681 | 10439 | 10766 | 11037 |
| HATCHERY |  |  |  |  |  |  |  |  |  |
| WILD | 2728 | 2843 | 2946 | 2138 | 2320 | 2372 | 1637 | 1724 | 1797 |
| GRAND TOTAL (F,M,J) | 28191 | 28987 | 29586 |  |  |  |  |  |  |

The program also has a second "what if" option built into it. The program allows an arbitrary trapping rate to be set and confidence intervals can be found using that trapping rate with the current trapping data.

Table $5.90 \%$ confidence intervals with the trapping rate at $13 \%, 2006$.

| Group/rearing type/total <br> age | lower | Female | upper | lower | Male | upper | lower | Jacks | upper |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| OUT OF BASIN | 171 | $\mathbf{1 9 6}$ | 219 | 76 | $\mathbf{9 3}$ | 108 | 74 | $\mathbf{8 9}$ | 105 |
| SNAKE R. HATCHERY | 2161 | $\mathbf{2 2 7 6}$ | 2372 | 3349 | $\mathbf{3 5 1 6}$ | 3651 | 5569 | $\mathbf{5 8 1 8}$ | 6013 |
| WILD | 1448 | $\mathbf{1 5 3 6}$ | 1613 | 1134 | $\mathbf{1 2 0 9}$ | 1271 | 872 | $\mathbf{9 3 1}$ | $\mathbf{9 8 7}$ |

The 2005-2006 trapping rate was $13 \%$. Does it make a difference if the trapping rate was higher or lower? We compared $13 \%$ to $6 \%$ and $20 \%$ trapping rates for groups collapsed to out-of-basin, Snake R. hatchery, and wild. If the trapping rate was set to $6 \%$, the out of basin confidence intervals were comparable to the results found when the actual trapping rate of $13 \%$ was used. The other confidence intervals were generally wider. For example, the confidence interval for
the grand total was 14696 to 16293 . The results obtained with the $13 \%$ sampling rate were 15079 to 16117.

Table 6. $90 \%$ confidence intervals if trapping rate was $6 \%, 2006$.

| GROUP | lower | female | Upper | Lower | Male | upper | lower | jack | upper |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| OUT OF BASIN | 169 | $\mathbf{1 9 6}$ | 220 | 75 | $\mathbf{9 3}$ | 109 | 73 | $\mathbf{8 9}$ | 105 |
| SNAKE R.HATCHERY | 2110 | $\mathbf{2 2 7 6}$ | 2391 | 3276 | $\mathbf{3 5 1 6}$ | 3685 | 5442 | $\mathbf{5 8 1 8}$ | 6064 |
| WILD | 1422 | $\mathbf{1 5 3 6}$ | 1621 | 1111 | $\mathbf{1 2 0 9}$ | 1278 | 856 | $\mathbf{9 3 1}$ | 990 |
| GRAND TOTAL (F,M,J) | 14696 | $\mathbf{1 5 6 6 5}$ | 16293 |  |  |  |  |  |  |

If the trapping rate was set to $20 \%$, the confidence intervals should be shorter. In some cases they were and in some cases they were not. Underlined values in Table 7 were tighter under $20 \%$ sampling when compared to the same confidence limits under $13 \%$. The most notable improvement in confidence interval width was for the grand total.

Table 7. $90 \%$ confidence intervals if trapping rate was $20 \%, 2006$.

| GROUP | lower | female | upper | lower | male | upper | lower | jack | upper |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| OUT OF BASIN | 172 | 196 | 218 | 76 | 93 | 108 | 74 | 89 | 104 |
| SNAKE R. HATCHERY | $\underline{\underline{2173}}$ | 2276 | 2366 | $\underline{3378}$ | 3516 | $\underline{3624}$ | $\underline{5620}$ | 5818 | 5981 |
| WILD | 1455 | 1536 | $\underline{1606}$ | 1145 | 1209 | 1274 | 876 | 931 | 985 |
| GRAND TOTAL (F,M,J) | 15212 | 15665 | 16034 |  |  |  |  |  |  |

IV. Comparison of 2005 and 2006 results

The individual groups were not comparable in 2005 and 2006, but we could compare the confidence intervals for out-of-basin, Snake River hatchery, and wild groups for the two years. During 2005 we only had adult and jack estimates so female and male data from 2006 were collapsed to adults for comparisons in Table 8. The run estimate was 12\% higher in 2006 (13985 vs. 15665).

Table 8. Comparison of 2005 and $200690 \%$ confidence intervals.

| Group | L | Adults | percent | U | L | Jacks | percent | U |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2005 |  |  |  |  |  |  |  |  |
|  | 1286 | 1367.1 | 11.7\% | 1446 | 126 | 148.1 | 6.3\% | 168 |
|  | 6876 | 7162.4 | 61.5\% | 7446 | 1784 | 1880.4 | 80.1\% | 1986 |
|  | 2986 | 3108.6 | 26.7\% | 3252 | 288 | 318.7 | 13.6\% | 350 |
| GRAND TOTAL (adults+jacks) | 13434 | 13985 | 14523 |  |  |  |  |  |
| 2006 |  |  |  |  |  |  |  |  |
|  | 258 | 288 | 3.3\% | 317 | 73 | 89 | 1.3\% | 105 |
|  | 5593 | 5792 | 65.6\% | 5959 | 5624 | 5818 | 85.1\% | 5981 |
|  | 2631 | 2746 | 31.1\% | 2847 | 873 | 931 | 13.6\% | 981 |
| GRAND TOTAL (adults+jacks) | 15079 | 15665 | 16117 |  |  |  |  |  |

The proportions of Snake River hatchery fish were comparable for both years for both adults and jacks. The proportions of out-of-basin and wild fish were different for adults. There were relatively fewer out-of-basin adults in 2006 and more wild fish.

All but one of the confidence intervals in this table show that we know the true numbers of fish arriving at Lower Granite dam in these categories within 10\%. For out-of-basin adults in 2006, the confidence interval was 258 to 317 . The target confidence interval was 259 to 317 . We were just outside the lower target. At the out-of-basin, hatchery, and wild level, sampling was adequate in both years.

In 2005 the coefficient of variation (CV) of the estimate was std error/estimate $=323.4 / 13985=$ $2.3 \%$. In 2006 the CV was $315.9 / 15665=2.0 \%$. The precision for both years was comparable.

## V. Discussion

The statistical intervals documented in this report were sensitive enough to detect differences in run sizes and gross composition in 2005 and 2006. The confidence intervals for total fish returning ( 13434 to 14523 and 15079 to 16117) do not overlap. The numbers of strays, Snake River hatchery, and wild fish can be seen to be different in the 2 years.

Interestingly, the proportion of jacks returning to Lower Granite dam was different in the two years. For 2005 , the proportion was $2347 / 13985=17.5 \%$ and for 2006 the proportion was $6839 / 15665=43.6 \%$. The confidence intervals for jacks do not overlap for the two years.

It was clear from the 2005 and 2006 analyses that we were not able to precisely estimate the numbers of fish returning by group in all cases. The confidence interval lower and upper limits for each group rarely were within $10 \%$ of the estimate. We do much better at the out-of-basin, hatchery, wild/age level (Table 3). We do even better at the out-of-basin, hatchery, wild level (Tables 5 and 8 ). We know the total numbers of fish returning within $10 \%$.

In retrospect, constructing the run composition by female, male, and jack was a decided improvement in 2006. Since age at return and thus composition of females are different from males, the estimates were greatly improved by dividing adults in to females and males for the calculations. Managers need to know sex as well as age, The drawback to this separation of adults into female and male is that some of the individual numbers were smaller and, hence, our confidence intervals did not meet the $10 \%$ target. Where the numbers were adequate, however, we did a good job of estimating returns by sex and age.

## Uncertainty related to origin of fish after CWT and unassociated assignments

Addendum 1 lists the final groupings of untagged hatchery fish that were not assigned to CWT or unassociated hatchery release groups. Each of the individual groups in Addendum 1 were included in Table 2, but the final assignments were not apparent from the name of the groups.

The "Inbasin unm/untag hatchery fish from unknown release sites" and "AD only hatchery fish from unknown release sites" (Addendum 1) were assigned to the Snake R. Hatchery group in Table 3. Since unassociated releases in the Snake R. did not have CWTs associated with them, SARs of fish from similar sites but from different return years were used to estimate their returns. It is possible that we underestimated the number of unassociated returns and the unm/untag fish in this group are actually from unassociated releases. In addition, because of uncertainty related to scale analysis, we suspect some proportion of these fish may be from out of basin, but we do not know to what extent.

The "Possible HSTRAY unm/untag sub" and "Possible HSTRAY AD only sub" groups were assigned to the Snake R. Hatchery group (Table 3) because CWT recoveries shed doubt on the magnitude of the estimated out of basin return using scale determinations. It is also possible that some of the Snake R. hatchery subyearlings reared at Umatilla Hatchery and Oxbow hatcheries (unassociated releases) were identified as HSTRAY by scale analysis. We do not have enough scale data from CWT fish from those hatcheries to determine if the scales have patterns similar to out of basin fish. Then again, it is possible that these fish were from out of basin unassociated releases, but we have no way of telling if that was the case.

The "Unknown hatchery yrl" were assigned to the out of basin group in Table 3. There is a lot of uncertainty regarding this group. Releases of yearling fall Chinook in the Snake R. basin have been essentially $100 \%$ marked or tagged over recent years. Yearling fall Chinook are also reared at Bonneville Hatchery but they are supposed to be $100 \%$ marked as well. Another option would be that the fish are untagged yearling releases of summer Chinook from the upper Columbia River. Scale analysis can only determine the age of the yearling hatchery fish, not origin so we rely solely on CWT data to determine the origin of yearlings.

There are many uncertainties related to scale analysis. Efforts are being made to continue to refine scale analysis for origin determinations. It is important that representative tag groups continue for each hatchery release to minimize uncertainty related to estimating the run composition at LGR.

Addendum 1. Presumed origins of untagged hatchery fish that could not be assigned to CWT or unassociated hatchery release groups.

| Final groupings | Scale origins | Run Reconstruction <br> Assignments |  |
| :--- | :--- | :--- | :--- |
|  | Individual groups (from Table 2) |  |  |

## Differences between determination of origins in 2005 and 2006 datasets

In 2005, HSTRAY fish were assigned out of basin, which is different from what was done for 2006 after discrepancies were noted in blind tests. Origins for other fish were assigned in the same manner each year. This report compares the statistical confidence intervals for out of basin, Snake River hatchery, and Snake River wild adults and jacks. Although the differences in estimates are partly due to differences in HSTRAY assignment, the assessment of precision as measured by the confidence interval widths is still relevant.

# Appendix J: Recoveries of Wire Tagged LFH/Snake River Hatchery Origin Fall Chinook Outside of the Snake River Basin in Return Year 2006 

(Includes recoveries of fish from the following release sites: LFH onstation and Couse Creek Boat Launch on the Snake River, and the Grande Ronde near the Cougar Creek, downloaded from RMIS 5/19/08. This data was not expanded for tag loss, sample detection method, or fishery.)

Appendix J. Locations and estimated totals of LFH/Snake River origin wire-tagged fish recovered during 2006. Based upon 5/19/08 download of CSV file from RMIS. Wire recoveries reported in this table are from the following release sites: Lyons Ferry Hatchery on-station and Couse Creek Boat Launch on the Snake River, and the mouth of Cougar Creek on the Grande Ronde River. Data for untagged fish associated with the wire-tagged fish are not included. This data was not expanded for tag loss, sample detection method, or fishery.

## 2004 run composition to Lower Granite Dam

A total of 15,845 fall Chinook passed the counting window (i.e. arriving at) at Lower Granite Dam (LGR) in 2004 of which 2,315 were wild (natural origin). This data does not include returns to the Tucannon River or estimates of fish trapped and killed at Lyons Ferry Hatchery because they are all downstream of Lower Granite Dam.

The composition of the fall Chinook arriving at LGR by release group with details on tag code, age, release age and site is summarized in Table 1. The release groups are wild (natural spawn) fall Chinook, LFH fall Chinook, supplementation/mitigation fall Chinook released above LGR and out-of-Snake-River-basin strays. In our summaries we show reservoir rearing estimates for wild fish, but not for hatchery fish. Reservoir rearing refers to a fish that naturally has a subyearling life history pattern, that ends up remaining in freshwater for another year, essentially leaving as a yearling. Data indicates reservoir rearing occurs with hatchery fish as well but we do not know to what extent so that data is not included here.

Table 1. Composition of fall Chinook to LGR Dam by CWT, origin, and age 2004. Note: the stray from Feather River Net Pen was not expanded.

## Estimating composition of run to Lower Granite Dam during the trapping period

Trapping began on September 2 and ended on November 24 (Appendix 1). The trap was set to open four times each hour, resulting in fish being trapped $15 \%$ of the time, 24 hours per day between Septeber2 and September 9. There were two interruptions in the trap operation so the effective trap rate for September 3 and 5 was $13.75 \%$ (see Appendix for details). The trap rate was $13 \%$ from September 9 to September 24.

## Databases used for estimates

In this report, trap data refers to data collected at the LGR Trap and processing data refers to data collected from fish hauled to and processed at LFH and NPTH (Appendix 2). While there is more sampling data in the processing database, only the trap database has information on date of arrival at LGR for fish. Thus the former is used to estimate composition and the latter is used to estimate run timing. The trap data also is the only place where data can be found for fish released directly from the trap at LGR.

The differences between the trap and processing data are apparent when estimating sex ratios, adult to jack ratios, and even species. Early in the season it is difficult to distinguish males from females so it is not uncommon to find more females in the processing data than in the trap data. In addition, fish may fit the jack size criteria at the trap but 2 months later they may fit the adult criteria due to kipe development. Some fish identified as fall Chinook at the trapping site were later reclassified as summer Chinook when their CWTs were processed.

## Trapping data

The trapping data was used to the following purposes:
-Estimate the numbers of fish hauled to LFH.
-Determine the hatchery/wild composition per week based on scales collected at the trap which in turn was used to create a regression so window counts of unmarked fall Chinook adults and jacks during pre and post trapping periods could be divided into wild and unmarked hatchery estimates.
-Estimate the composition of the released fish from the trap at Lower Granite Dam
Processing data

The processing data was used to estimate the release strategy and age composition of the majority of fish arriving at LGR during the trapping period that were hauled to the hatcheries.

The various origins enumerated include natural origin, Lyons Ferry Hatchery, Idaho Power Company (IPC) mitigation releases, supplementation program releases, and out-of-basin (strays). The composition of the various release strategies was determined from the various marks consisting of CWT, Blank Wire Tags (BWT), Agency wire tags (09BLANK or 63BLANK), PIT tags, Ad-clips, and VIE tags. For example:

- AD-only (no other marks or tags) subyearling (either stray or non-stray as determined from scale patterns) $=$ IPC. The strays were presumed to be IPC because no other ad-only subyearling fall Chinook are produced in the basin and the estimated number of AD only fish associated with CWT releases was 5 fish. Since none of the release groups totaled one fish between the groups, all fish were assigned to IPC mitigation. Some of the IPC fish were reared at Umatilla, hence may cause the scale patterns to indicate an out of basin stray),
- Fish with left red (LR) VIE are from LFH yearling on-station releases,
- Fish with left blue (LB) VIE are from Captain John Acclimation Facility yearling releases,
- Fish with right green (RG) VIE are from Pittsburg Landing Acclimation Facility yearling releases,
- Fish with left green (LG) VIE are from Big Canyon Acclimation Facility yearling releases.

## Resolving differences between the Trapping and Processing databases

To distinguish between the two trapping rates, fish trapped at LGR during the $15 \%$ trapping period were given a PIT tag. Because of PIT tag loss (see PIT tag issues below) there were fish that we were unable to assign to a trapping rate (unknown trap rate group). To assure that the correct numbers of fish were expanded for each trapping period we had to use the LGR trap data to determine the numbers of fish hauled to the hatcheries in each trapping period. Adjustments to the processing data were made so the total numbers of fish in each trapping period were the same as the trapping data (Appendix 3).

## Estimating composition of run to Lower Granite Dam during the trapping period

## Estimating composition of wire tag group

Wire tagged groups are processed separately from untagged groups. Fish with wires that were undecoded because the tag was lost or the fish was released, had their composition estimated based on recovered/decoded wires, based on sex, clip, and VI. All fish with wire tags were hatchery origin. Blank wire tags and agency wire tags are not coded wire tags. Blank wire tags and agency wire tags that were recovered were considered strays from non-Snake River releases, since Snake River basin releases do not use Blank or Agency wire.

## Estimating hatchery/wild composition of no-wire fish

Untagged processed fish had origin and age determined from a combination of scale analysis (John Sneva, WDFW), PIT tags, VI tags, and presence/absence of ad-fin clip. Some unmarked untagged strays, all natural origin, and some summer Chinook were identified solely from the scale analysis. Any fish with an ad-clip or a VI tag was considered to be hatchery origin. Fish whose scales were not readable were partitioned into the untagged groups according to sex, age, presence/absence of ad-clip, and VI data.

Origins were estimated for fish whose scales were not readable by using the composition of the readable scales to determine hatchery and wild origins and ages. To determine which releases contributed to the untagged hatchery returns we assign untagged fish to their associated CWTs based on juvenile release data. If any hatchery fish are left after we subtract them from the untagged hatchery fish group then we estimate the number of fish that came from untagged releases, "unassociated". To estimate extent of returns of these "unassociated" fish smolt-to-adult returns of CWT fish from the same release location although from different years may be used. Any fish remaining after those estimates are made are placed in an "unknown" category. In years where the stray rate is low based on CWT returns we may estimate that these remaining unknown fish are from inbasin untagged hatchery releases but we cannot determine which release site released the fish.

## Origin and age of fish during trapping period

The composition was estimated from fish released at the Lower Granite Trap and was combined with the composition data generated from fish processed at the hatcheries to come up with an overall comp of the run during the trapping period. Table 2 presents the composition of the fish in the trap samples.

Table 2. Composition of fish in 2004 trap samples, expended for trap rate.

## Estimating composition of run to Lower Granite Dam before and after the trapping period

## Use window for counts during pre and post trapping period

Nighttime/video counts were not made in 2004. We took the daily 16-hour direct window counts and 10 hour video counts and expanded the clipped and non clipped counts separately for 10 minute hourly breaks (direct counts) and 6 hour shortfall in video counts for the adults and jacks separately and then expanded each count by 0.965 to account for night time passage ${ }^{3}$. The expansions were summed before rounding. Expanding the window counts this way will make the counts not match the total counts provided by WDFW (Steve Richards) to the COE.

## Correct database for summer Chinook

The trap database contained 14 summer Chinook (Appendix 4): 12 adults (4 clipped and 8 un-clipped) and 2 Jacks (both un-clipped). These fish were removed from the trap database. These fish were also expanded by the appropriate trap rate for the date of capture and then the expanded numbers were subtracted from the same day's 24 -hour window counts. The summer Chinook expanded to 85 adults and 15 jacks. Two non-clipped adult summer Chinook were hauled to LFH, all other summer Chinook were released above Lower Granite.

## Correct database for recaptures

Some of the fish released from the LGR trap were later recaptured and released again. All recaptures occurred during the $13 \%$ trap rate period. These fish were removed from the trap database (Table 3).

[^5]Table 3. Estimated unique numbers of fall Chinook released from the LGR trap, 2004.

| Summary of Fall Chinook Released from LGR Trap in 2004 during 15\% trap period |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | :---: |
|  | Unknown origin | Wild | Hatchery | Total |  |  |
| Fish labled as released | 0 |  | 10 | 14 | 24 |  |
| Recaptures | 0 | 0 | 0 | 0 |  |  |
| Fish to count as released | 0 | 10 | 14 | 24 |  |  |

Summary of Fall Chinook Released from LGR Trap in 2004 during 13\% trap period

|  | Unknown origin | Wild | Hatchery | Total |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Fish labled as released | 35 | 79 | 54 | 168 |
| Recaptures | 31 | 38 | 20 | 89 |
| Fish to count as released | 4 | 41 | 34 | 79 |

Summary of Fall Chinook Released from LGR Trap in 2004 during combined trapping periods

|  | Unknown origin | Wild | Hatchery | Total |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Fish labled as released | 35 | 89 | 68 | 192 |
| Recaptures | 31 | 38 | 20 | 89 |
| Fish to count as released | 4 | 51 | 48 | 103 |

## Reconcile difference in jack proportions between window counts and trap samples

The proportion of fall Chinook jacks in the trap did not match the proportion of jacks observed during window counts (Table 4).

Table 4. Comparison of fall Chinook jack proportions in 2004 window counts and trap sample

|  | Window count | Trap sample |
| :---: | :---: | :---: |
| adult | 12,340 | 19,291 |
| jack | 6,271 | 3,422 |
| total | 18,611 | 22,714 |
| $\%$ jack | $33.7 \%$ | $15.1 \%$ |

Figure 1. Comparison of 2004 jack proportions in trap sample with window counts.

The proportions of jacks in the trap samples were considered more accurate than the proportions from the window counts (Figure 1). Fish in the trap were measured (fork length) whereas fall Chinook size estimates are made as fish swam between two pieces of tape placed on the fish counting window. Therefore in Table 5 we adjusted the pre trapping period window counts of jacks to match the trap proportions but did not change the ad-clip proportions (which would have affected the estimate of wild fish). No change was required for the post trapping period window counts because none were observed.

Table 5. Pre trapping period window counts adjusted for difference between window and trap jack proportions in 2004.

|  | original window <br> count |  <br> unmarked numbers | adjustment for <br> unmarked fish |
| :--- | ---: | ---: | ---: |
| Adults | 56 | 70 |  |
| clip | 174 | 218 | 1.254014 |
| no clip | 230 | 288 |  |
| total |  |  |  |
|  |  | 10 |  |
| Jacks | 22 | 37 | 0.447145 |
| clip | 83 | 47 |  |
| no clip | 106 |  |  |
| total jacks |  |  |  |

## Estimating the numbers of wild fish arriving at Lower Granite Dam before and after trapping period

To estimate the hatchery-wild composition during the pre-trapping period, we presumed wild fish returned earlier than hatchery fish. The last year we were able to begin trapping on August 18 was during the 2002 run. Data from 2002 is presented in Figures 2 and 3 for compare with the pre-trapping estimates for 2004. The 2002 data was not used to fit the regression.

To build the data used in the regression we estimated the proportion of wild fish in the unmarked return to LGR by week. The scales that were used for this part of the analysis were from the trap database because they could be associated with an arrival date at the trap. Of the unmarked fish, some are known to be hatchery fish based on presence of wire, VIE, or scale readings, and some are known to be wild fish through scale analysis. Unmarked untagged fish whose scales were unreadable are of unknown origin. We assumed that these unknown origin unmarked untagged fish had the same wild/hatchery proportion as fish whose scales had origin determinations.

We used an exponential decay regression of $\%$ wild Chinook among the non-adclipped fish over time in the trap data to estimate the proportion of non ad-clip fish in the window counts that is wild for the period prior and after trapping (Figures 2 and 3 ).

Figure 2. Expected trend in \% wild among non-clip adult in 2004. 2002 data was not used to fit the curve.

Figure 3. Expected trend in \% wild among non-clip jacks in 2004.

We applied the modeled wild-hatchery proportions to the window counts from the pre- and post-trapping period and estimate that 107 wild fall Chinook arrived before trapping and 0 arrived after the trapping period (Table 6).

Table 6. Estimated number of wild and hatchery fall Chinook arriving at LGR before and after the 2004 trapping period.

|  | Adults by length |  |  | Jacks by length |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
|  | wild | hatchery |  | wild | hatchery |
| pre-trap | 90 | 128 |  | 17 | 20 |
| post-trap | 0 | 8 |  | 0 | 0 |

## Composition of fish arriving at Lower Granite Dam during the pre-and post trapping period

The age composition of the wild fish estimated during trapping (processing data combined with fish released at LGR data) was applied to the estimated number of wild fish arriving before the trapping period. This was done because many more fish were scale sampled at the hatcheries than were collected at the trap.

It was presumed that the hatchery fish arrived in the same proportions pre- and post-trapping as they did during trapping. The age composition of the hatchery fish estimated during trapping (processing data combined with fish released at LGR data) was applied to the estimated number of hatchery fish arriving before and after the trapping period.

## Total wild and hatchery fish arriving at Lower Granite Dam

Compositions of fish estimated for the pre, during, and post trapping periods were combined, resulting in the run estimate of fish arriving at LGR (Table 1).

## Estimating the run past Lower Granite Dam

The total run past LGR is estimated by subtracting fallbacks or known downstream passage), the numbers of fish trapped at LGR that were hauled to the hatcheries and killed. Since recaptured fish were already removed from the run data there aren't any adjustments needed for that group.

## Subtract known downstream passage

The Juvenile Bypass/Collection Facility has an adult separator located below LGR Dam. The separator is part of the Juvenile Collection facility that collects fish moving downstream. The separator diverts adult sized fish away from the Juvenile Collection Facility and directly into the river. Since all of the fish observed at the Juvenile bypass facility originated from above LGR they are considered fallbacks because they had already been in the estimate of fish past LGR.

Table 7 summarizes the minimum number of fall Chinook adults and jacks diverted into the river through the adult separator. Except for the Juvenile Bypass Facility, we did not attempt to estimate any other fallback for 2004 as we did not have any data to estimate the numbers of fish that may have passed downstream via turbines, locks, spillway, etc. Downstream passage through the ladder is subtracted from the window counts.

Table 7. Total estimate of ad-clipped and unclipped fish passing downstream through the adult separator3 in 2004.

| 2004 | Clip | Adult Unclip | Total | Clip | Jack UnClip | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| September | 94 | 45 | 139 | 60 | 22 | 82 |
| October | 203 | 93 | 296 | 155 | 27 | 182 |
| Total | 297 | 138 | 435 | 215 | 49 | 264 |

Data from Fred Mensik (LGR Juvenile Collection Facility)

## Estimated spawning escapement

The numbers of hatchery fall Chinook that were trapped at Potlatch or volunteered into NPTH (Table 8) were subtracted from the fall Chinook that passed LGR to obtain the spawning escapement. No wild fish were removed above LGR in 2004.

Table 8. Hatchery fish Removed from the river above Lower Granite Dam either by trapping at Potlatch or volunteers to NPTH in 2004.

| Location | Hatchery <br> Adult | Hatchery <br> Jack | Wild <br> Adult | Wild <br> Jack | Total |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| Potlatch Trap <br> NPTH | 1 | 0 | 0 | 0 | 1 |
| Volunteers | 541 | 173 |  |  | 724 |
| Total |  |  | 8 | 2 |  |

## Discussion

## PIT tag Issues

Fish collected in the trap during the $15 \%$ trapping period were PIT tagged in 2004 in an effort to help identify fish collected at different trap rates more accurately. This was separate from fish that are PIT tagged as Juveniles or at other locations as adults. Unmarked/untagged fish were PIT tagged so scales and measurements could be collected at time of spawning rather than trapping. This was done in an effort to reduce workload for trapping crew.

It was not possible to track each PIT tagged fish tagged at the trap for several reasons. There were problems with recording PIT tag numbers. Some was done by hand with only the last four digits recorded. Some recording errors likely occurred. Some other PIT tagged fish were simply not found again, possibly due to some level of tag loss or reader errors. Some fish (especially females) are believed to lose PIT tags at spawning as tags have been recovered in incubation trays where they were mixed with eggs and also at the bottom of holding ponds.

We decided to not try and account for missing PIT tag data and fish and only use PIT tag data that can be tracked. This has the effect of sub sampling the trapped portion of the run.

Some PIT tagged fish were returned to the river below LGR and were not retrapped at the dam. Due to time constraints associated with PIT tag data accounting, we advise this method not be used in the future.

## Appendix

## Appendix 1. Chronology of window counts and trapping

August 18: Start counting fall Chinook 20 hours per day at the Lower Granite Dam window.
August 26: Start sort by code for University of Idaho. The sort by code diverted two fish into the trap: one on $8 / 27$ and one on $8 / 29$. One fish was operculum punched and the other fish was not. Both fish were released upstream with radio tags. Both were unmarked and not CWT tagged. Neither was seen again.

September 2: Begin trapping at a $15 \%$ rate 24 hours/day. All unmarked untagged fish were PIT tagged and was transferred to LFH. Any previously marked/tagged fish were also transferred to LFH but not PIT tagged.
September 3: Corps of Engineers turned off trap for two hours because of lack of section 10 permit. Adjustment the trap rate: $1-2 / 24$ hours $=91.7 \%$. There were no hourly trap counts so cannot adjust $\%$ trap rate using trap timing profile. If 10 fish in trap, then expanded number $=11$ fish.

September 5: Trap was turned off for two hours because tanks were full and truck was not available to haul fish to LFH. We decided based on daily counts and trap rates that this has a negligible effect on the data and would be ignored.

For September 3 and 5, trap was operated for 22 hours instead of 24 hours. $22 / 24=0.9167$ ( 8 $15 \%$ target trap rate $\times 0.9167=13.75 \%$ actual trap rate for these two days. For the 6 other days, the trap rate was $15 \%$.

September 10: Trapping was changed to $13 \%$ to avoid overwhelming the trap. Continue to PIT tag all unmarked untagged fish but not any previously marked/tagged fish.

September 14: Start PIT tagging only every third unmarked/untagged fish due to shortage of PIT tags. Because of the change to $13 \%$ trap rate, Debbie Milks PIT tagged the marked/tagged fish that were in the pond at LFH that were captured during the $15 \%$ trapping schedule. This was done to ensure these fish could be separated from the marked/tagged fish that were caught later. This operation had a high tag loss rate with only 76 of 100 PIT tags found later during scale collection.

October 19: Begin release of unmarked/untagged males and jacks because they were not needed for broodstock. Released fish were left operculum punched and scales were taken from every third fish.

October 27: Protocol was modified to clarify retention of caudal clipped fish (previous captures or volunteers). If no caudal clip present then all females and wire tagged fish were retained. If top caudal clip present (LFH volunteers), then wire tagged fish only were retained (others were all supposed to be males). If bottom caudal clip present (previously trapped and transported from LGR), then only wire tagged fish were retained. Scales were taken and left operculum punch given to released fish.

November 4: Release protocol was modified so that adipose-clip only females were retained. Wire tagged fish were still retained as well. Left operculum punch was given to any released fish.

November 24: Trapping ends.
December 15: Stop counting fall Chinook at the Lower Granite Dam window.

## Appendix 2. Chronology of fish hauls

September 2-8: Fish were hauled to LFH.
September 9-16: Fish were hauled to NPTH. These fish were all PIT tagged so they can be identified as captured at the $15 \%$ trap rate (marked and unmarked fish).

September 17-20: Fish were hauled to LFH.
September 21-22: Fish were hauled to NPTH.
September 23-November 22: Fish were hauled to LFH.

## Appendix 3. Unknown trap rate assignments.

Assignments of fish that were returned to the river from LFH were assigned to the $13 \%$ and $15 \%$ trap rates based on information about sex and wire status from the trapping and processing databases. Clip status of these fish was also estimated. It was necessary to make some adjustments in the wire status and sex of some of the fish. The process is outlined in spreadsheet named LFH2004CWT AND NPT04 ver10.xls.

Appendix 3 Table 1. Assigned composition of fish in 2004 unknown trap rate group released from LFH.

| clip | 13\% trap rate |  |  | 15\% trap rate |  |  | total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Male | Female | Jack | Male | Female | Jack |  |
|  | 46 | 2 | 5 | 3 | 1 | 1 | 58 |
| no clip | 290 | 37 | 55 | 21 | 14 | 10 | 427 |
| total | 335 | 40 | 60 | 25 | 14 | 11 | 485 |

## Appendix 4. Summer Chinook

The trap database contained 14 Summer Chinook: 12 adults (4 clipped and 8 un-clipped) and 2 Jacks (both un-clipped). These fish were removed from the trap database. These fish were also expanded by the appropriate trap rate for the date of capture and then the expanded numbers were subtracted from the same day's 24 -hour window counts. The summer Chinook expanded to 85 adults and 15 jacks. Table 12 shows the counts corrected for summer Chinook.
Two non-clipped adult summer Chinook were hauled to LFH, all other summer Chinook were released above Lower Granite.

[^0]:    1 The LSRCP Special Report refers to adult recoveries. That language was intended to differentiate adults from juveniles in the document (Dan Herrig USFWS, LSRCP, personal communication). The LSCRP mitigation goal was based upon 97,500 fall Chinook counted at McNary Dam in 1958, and with the expectation that 14,363 wild fall Chinook would persist in the Snake River through natural production. At that time adult and jack counts were combined to give a total count. Therefore the mitigation goal consists of jacks and adults, not just adults. Since mitigation goals were set up using window counts at dams, and minijacks (fish $<30 \mathrm{~cm}$ total length) are not counted at the dams, they were excluded from the mitigation goal calculations.

[^1]:    2 For this report wire refers to all CWT (coded wire tags), Blank wire (non-coded) tags, and Agency only (coded only with agency code) tags.

[^2]:    ${ }^{a}$ In the mark type column, visible implant elastomers (VIE) are designated by side and then color, i.e. LR denotes left red.

[^3]:    ${ }^{\text {a }}$ The 63BLANK wire fish reared in a reservoir or the estuary and reached the ocean as a yearling.

[^4]:    ${ }^{\text {a }}$ No counts (nc) were completed at the dam during that time of year.
    ${ }^{\mathrm{b}}$ No jacks were recovered during Tucannon River spawning ground surveys in 2004.
