## Acknowledgments

The Tucannon River Spring Chinook Salmon Captive Broodstock Program was the result of efforts by many individuals within the Washington Department of Fish and Wildlife (WDFW) and from other agencies.

We thank the Lyons Ferry Hatchery (LFH) Complex Managers, Harold "Butch" Harty, the late Don Peterson, Mike Lewis, Steve Rodgers, and Jon Lovrak for their coordination efforts and oversight of all hatchery operations during the length of the captive brood program. We thank Bruce Walters, Severin Erickson, and Steve Jones for their cooperation with hatchery sampling, providing information regarding hatchery operations and records, and input on evaluation and research activities. We also thank all the LFH personnel who provided day-to-day care of the captive broodstock and for their assistance with spawning, sampling, and record keeping. We are also indebted to Jerry Dedloff, Debbie Milks, Jule Presler, Mark Schuck and other staff members of the Snake River Lab that provided helpful assistance during spawning, PIT tagging, spawning ground surveys and smolt trapping.

We thank Julie Hoof and the WDFW tagging staff for their assistance in tagging the captive fish. Megan Heinrich from the Idaho Cooperative Fish and Wildlife Research Unit - University of Idaho provided the radio tags for tagging the captive adult outplants.

We sincerely thank personnel from the Nez Perce Tribe (NPT) and Confederated Tribes of the Umatilla Indian Reservation (CTUIR) who participated and provided comments during the development of the Tucannon Master Plan and for their continual input into the captive program. Without these respective agencies' support, this program would not have proceeded.

We thank the Bonneville Power Administration (BPA) for their financial support for the captive broodstock program. Peter Lofy provided invaluable support and assistance regarding the captive brood program contract. We are also indebted to Ed Crateau and Dan Herrig of the U.S. Fish and Wildlife Service Lower Snake River Program for their financial support of the captive brood program from 1997-1999. Cost share in the form of both fish culture and research support from the LSRCP has been invaluable throughout the project, and will continue as progeny return to LSRCP facilities.

Finally, we thank Glen Mendel, Jon Lovrak, and Andrew Murdoch of the WDFW, and Peter Lofy, BPA, for their critical reviews and helpful comments on the draft report.

## Abstract

This report summarizes the objectives and accomplishments of the Tucannon River Spring Chinook Salmon Captive Broodstock Program. The WDFW initiated a captive program in 1997. The captive program collected sac fry from the hatchery supplementation program from five (1997-2001) brood years (BY) with additional sac fry collected from the 2002 BY in order to have extra captive males on hand to spawn. The overall goal of the Tucannon River captive program was for the short-term rebuilding of the Tucannon River spring Chinook salmon population, with the hope that natural production would sustain the population in the future. The project goal was to rear captive salmon selected from the supplementation program to adults, spawn them, rear their progeny, and release approximately 150,000 smolts annually into the Tucannon River between 2003-2007. This was expected to provide a return of about 300 adult fish to the Tucannon River of captive origin per year between 2005-2010. These smolts, in combination with the current conventional hatchery supplementation program and natural production, were expected to produce 600-700 returning adult spring Chinook to the Tucannon River each year from 2005-2010.

Selecting fry from parents based on Bacterial Kidney Disease (BKD) screening appeared to have benefited the program, as BKD was not an issue with the Tucannon captive broodstock as it has been with other Chinook salmon captive brood programs. Overall survival and health of captive brood adults was good throughout the duration of the program.

Adult spawners from the captive program were significantly smaller than conventional hatchery and natural origin fish. The captive broodstock produced significantly larger eggs, but egg quality was poor, with high egg mortality. The large eggs in small adults resulted in significantly lower fecundity, relative fecundity, and reproductive mass in captive females compared to conventional hatchery and natural origin females of the same age.

During 2002, adult captive broodstock determined to be in excess of broodstock needs were outplanted into the upper Tucannon River in order to stay within the approved release goal of 150,000 smolts. Due to the low frequency of natural spawning by released fish, high mortality due to evidence suggesting predation and illegal harvest, and high egg mortality in the hatchery during 2002, the priority for excess fish in the future was changed. The co-managers agreed to spawn excess adults, and release their progeny as parr.

The captive program did provide additional smolts for release that otherwise would not have occurred had the program not been in place. Downstream survival rates of smolts based on PIT tagging revealed that survival tended to be higher every year for conventional hatchery fish compared to captive progeny. However, with the exception of the 2006 brood year, differences were not significant.

As anticipated, due to their protection in the hatchery environment, egg-to-parr, parr-to-smolt, and egg-to-smolt survivals of captive progeny and conventional hatchery fish were higher than natural origin fish. However, egg-to-parr and egg-to-smolt survivals were higher for conventional hatchery fish than captive progeny. Smolt-to-adult return (SAR) survival has effectively been $<0.02 \%$ for the first five years of the captive program compared to SARs of
$0.13 \%$ and $1.07 \%$ for conventional hatchery and natural origin fish, respectively. Captive progeny size at release was increased from 30 g /fish to $50 \mathrm{~g} /$ fish for the 2005 and 2006 brood years. We are cautiously optimistic this change will increase SAR survival.

Based on adult returns from the 2000-2005 brood years, captive program produced only 0.17 adults for every spawner which is considerably lower than naturally reared salmon that produced 0.67 adults for every spawner. Conventional hatchery reared fish produced 1.66 adults per spawner and was usually the only group to return adults above replacement levels. It is unknown whether hatchery domestication effects or other unknown factors have played a role in the poor returns, as the captive progeny and conventional hatchery fish are reared and released in the same manner. Based on the results to date, the Tucannon River spring Chinook captive broodstock program has been unsuccessful in achieving its adult return goals.

The WDFW LSRCP evaluation program will continue to document returning adults from the captive program and compare their survival to survivals from the conventional hatchery supplementation program and natural origin fish. A final assessment of the captive program will be submitted for publication in a peer-reviewed journal after the final adults return in 2011.

## Introduction

## Reporting Period

This report summarizes the major accomplishments of the Tucannon River spring Chinook ${ }^{1}$ salmon (Oncorhynchus tshawytscha) captive broodstock ${ }^{2}$ program from 1 October 1999 to 30 September 2009 (FY2000 - FY2009). This report, while originally intended to cover activities accomplished exclusively under the BPA funded program, includes activities funded by the U.S. Fish and Wildlife Service Lower Snake River Compensation Plan (LSRCP) program as well for comparative purposes. This was done to provide readers with a complete timeline of the activities that have occurred over the course of the program and compare the captive program to the conventional hatchery supplementation program and natural origin fish during the same time period. The genetic (microsatellite DNA) analysis for this program will be covered in a separate report. For detailed information on individual brood years the reader is directed to the annual reports located on the BPA website. Although this is the final report to be submitted to BPA, the last captive progeny adults are expected to return to the Tucannon River in 2011. Continued yearly assessments will occur under LSRCP funding. A final assessment of the captive program will be submitted for publication in a peer-reviewed journal after the final adults return in 2011.

## Tucannon River Spring Chinook Program Overview

Prior to 1985, artificial production of Chinook in the Tucannon River was limited to only two fry releases in the 1960s (WDFW et al. 1999). The Washington Department of Fisheries released 16,000 Klickitat ( 2.3 g fish or 197 fish/lb) and 10,500 Willamette ( 2.6 g fish or 175 fish $/ \mathrm{lb}$ ) stock Chinook into the Tucannon River in August 1962 and June 1964, respectively. The out-planting program was discontinued after a major flood destroyed the rearing ponds in 1965. Neither of these releases is believed to have returned any significant number of adults. After completion of the four lower Snake River dams, the LSRCP program was created to provide hatchery compensation for the loss of spring and fall Chinook salmon, and summer steelhead (O. mykiss) in the Snake River resulting from construction and operation of the four lower Snake River power dams (USACE 1975). In 1985, Washington Department of Fish and Wildlife (WDFW) began the hatchery Chinook production program in the Tucannon River by trapping wild (unmarked) adults for the hatchery broodstock. Hatchery-origin fish have been returning to the Tucannon River since 1988. The hatchery broodstock since 1989 has consisted of natural and hatchery-origin fish.

In 1992, the National Marine Fisheries Service (NMFS) listed Snake River spring/summer Chinook salmon as "endangered" (April 22, 1992 Federal Register, Vol. 57, No. 78, p 14653), which included the Tucannon River stock. The listing status was changed to "threatened" in 1995 (April 17, 1995 Federal Register, Vol 60, No 73, p 19342). From 1993 to early 1998, WDFW operated the hatchery supplementation program under Section 10 direct take permit

[^0]\#848 for artificial propagation and research. From late 1998 to 2003, WDFW operated both the supplementation and captive program under Section 10 direct take permits \#1126 (artificial propagation), and \#1129 (research), and since 2003 the program has operated under the Tucannon River Spring Chinook Hatchery and Genetic Management Plan.

The Endangered Species Act (ESA) allows for "the use of all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the measures pursuant to the Act are no longer necessary" (ESA 1973). Consistent with that provision, WDFW and the co-managers [The Confederated Tribes of the Umatilla Indian Reservation (CTUIR) and the Nez Perce Tribe (NPT)] decided in 1997 to implement the Tucannon River captive program to sustain and potentially recover this listed population. Both of the hatchery programs (conventional supplementation and captive) are being conducted with the recognition that artificial propagation may have potentially deleterious direct and indirect effects on the listed fish (Hard et al. 1992; Cuenco et al. 1993; Busack and Currens 1995; Campton 1995). These effects may include genetic and ecological hazards that cause maladaptive genetic, physiological, or behavioral changes in donor or target populations, with attendant losses in natural productivity (Hard et al. 1992). Araki et al. (2007) found that even a few generations of domestication may have negative effects on natural reproduction of fish in the wild. Because the effects of a captive brood program expose the population to artificial selection for a longer part of the life history, its effects may be exacerbated, compared to a conventional supplementation hatchery program. However, WDFW and the co-managers believed the risk of extinction in the Tucannon River was high enough to warrant a short-term, limited intervention in addition to the supplementation program. This program was pre-defined to last for only onegeneration cycle (five brood years), to minimize potential negative effects due to the short-term nature of the program.

Annual adult returns between 1985-1993 were estimated to be 400-750 natural and hatcheryorigin fish combined (Figure 1). In 1994, the adult escapement declined severely to less than 150 fish, and the run in 1995 was estimated at 54 fish. In 1995, WDFW started the captive program, but discontinued it based upon higher returns predicted for 1996 and 1997. Unfortunately, the 1996 and 1997 returns were not as strong as predicted. In addition, major floods in 1996 and 1997 on the Tucannon River was presumed to have destroyed most of the natural production for both brood years. Moreover, an $80 \%$ loss of the hatchery egg take occurred in 1997 due to a malfunction of a water chiller that cold shocked the eggs. Because of the lower returns, and losses to both natural and hatchery production, the Tucannon River spring Chinook captive program was re-initiated with the 1997 brood year.

Figure 1. Total estimated escapement of Tucannon River spring Chinook salmon from 19852000.

Key to the Tucannon River Chinook restoration effort will be whether or not the natural population can consistently return above the replacement level. Since 1985, WDFW has monitored and estimated the performance of the natural population for comparison to the conventional hatchery program as part of the LSRCP program (USFWS 1998). Monitoring efforts to date have shown the natural population below replacement almost every year (Figure 2). Unless the natural population returns to a point above replacement, the overall goal of the Tucannon River Chinook restoration program will not be met.

Figure 2. Return per spawner (with replacement line) for Tucannon River spring Chinook salmon for the 1985-2004 brood years (2004 brood year incomplete).

## Tucannon River Watershed Characteristics

The Tucannon River is a third order stream that empties into the Snake River between Little Goose and Lower Monumental dams approximately 622 river kilometers (rkm) from the mouth of the Columbia River (Figure 3). Stream elevation rises from 150 m at the mouth to $1,640 \mathrm{~m}$ at the headwater (Bugert et al. 1990). Total watershed area is about $1,295 \mathrm{~km}^{2}$. Mean discharge is $4.9-\mathrm{m}^{3} / \mathrm{sec}$ with a mean low of $1.7-\mathrm{m}^{3} / \mathrm{sec}$ (August) and a mean high flow of $8.8-\mathrm{m}^{3} / \mathrm{sec}$ (April/May). Chinook typically spawn and rear above Tucannon rkm 40. WDFW and the comanagers believe producing smolts will maximize recovery efforts from the captive and conventional hatchery programs, and acclimated releases in the upper watershed have the best chance for high survival and return to the best spawning and rearing habitat.

Figure 3. Location of the Tucannon River Basin, a tributary of the Snake River, and locations of Lyons Ferry Hatchery, Tucannon Hatchery, and Curl Lake Acclimation Pond.

It is hoped that initiatives for habitat improvement within the Tucannon Basin (BPA funded Tucannon River Model Watershed Program and Subbasin Plan, and the State of Washington Governor's Salmon Recovery Plan) that are aimed at increasing in-river survival, improved ocean conditions, and continued adult and juvenile passage improvements at Federal Columbia River Power System (FCRPS) dams, will be enough to return the natural population productivity to above the replacement level. For example, broad based goals of the Tucannon Model Watershed Program are to: 1) restore and maintain natural stream stability, 2) reduce water temperatures, 3) reduce upland erosion and sediment delivery rates, 4) improve and re-establish riparian vegetation, and 5) increase amounts of large woody debris. Managers hope that these habitat recovery efforts will ultimately increase survival of naturally reared Chinook in the river. While this will only provide an increase to juvenile population numbers (parr or smolts), greater numbers of smolts should return more adult fish to the Tucannon River even if passage problems and ocean conditions remain unchanged. The captive program was intended to provide a quick increase in the number of adults that will produce progeny to take advantage of improved habitat.

## Facility Descriptions

The program utilizes three different WDFW facilities: Lyons Ferry Hatchery (LFH), Tucannon Fish Hatchery (TFH), and Curl Lake Acclimation Pond (AP). Lyons Ferry Hatchery is located on the Snake River (rkm 90) at its confluence with the Palouse River (Figure 3). LFH was constructed with funds provided by the U. S. Army Corps of Engineers, and has subsequently been funded through the LSRCP program of the U.S. Fish and Wildlife Service, contracted as a direct cost by BPA. The LFH is used for adult broodstock holding and spawning, and incubation and early life stage rearing until production marking. Fifteen $1.2-\mathrm{m}$ diameter circular starter tanks were purchased when the captive program was started in 1995. In 1999, LSRCP purchased and supplied the funding for installation of eight $6.1-\mathrm{m}$ diameter circular rearing tanks for the adults, and for relocation of the small circular tanks. The tanks were installed during August and September of 1999 in the captive rearing area at LFH. During 2000, BPA supplied funding for security fencing around the broodstock rearing area.

The TFH, located at rkm 59 on the Tucannon River (Figure 3), has an adult collection trap onsite. Following marking at LFH, juveniles are transferred to TFH to rear through winter. In midFebruary, the fish are transferred to Curl Lake AP for a minimum of four weeks of acclimation. Curl Lake AP is a 0.85 ha natural bottom lake with a mean depth of 2.8 meters (pond volume estimated at $22,203 \mathrm{~m}^{3}$ ). Sometime between the middle of March and the beginning of April, the pond exit is opened and the fish are allowed to volitionally emigrate from the lake until the third week of April when they are forced out.

## Goal

The captive goal was to collect 290,000 eggs/year from captive females when three complete age classes (ages 3 to 5) were spawned concurrently. Under the original program design, these eggs were expected to produce about 150,000 smolts for release from Curl Lake AP. Depending on smolts produced each year this should provide a return of about 300 adult fish of captive origin per year from 2005 to 2010 if a survival rate of $0.2 \%$ to the weir was achieved. These fish combined with fish from the conventional hatchery program and natural production from the river were expected to return 600-700 fish annually between 2005-2010. While this is still well below the LSRCP mitigation goal, it would return the in-river population level to a pre-1994 level. As described in the Tucannon Master Plan, measures have been taken to minimize and mitigate potential genetic and/or ecological hazards of this program to the listed population (WDFW et al. 1999).

## Source of Captive Brood Population

The captive population was selected from sac fry produced from the conventional hatchery program during the 1997-2001 BYs (WDFW et al. 1999). Because males mature at an earlier age than females, additional sac fry were collected from the 2002 BY to have a sufficient number of males available at the end of the program to cross with captive females. The conventional hatchery broodstock consist of both natural and hatchery returns (generally 1:1 ratio). Returning hatchery fish used in the conventional hatchery broodstock are verified to have come from the

Tucannon River stock through CWT verification. Collection of eggs/fry from the conventional hatchery program was done to lessen the effects of removing more fish from the natural population. Also, disease history and origin of parents would be known, and the overall effect to the conventional hatchery program would be minimal.

During the spawning process in the conventional hatchery program, the eggs of two females were split in half with each lot fertilized by a different primary male (each male also acts as a secondary male). Due to the relatively small population size, a $2 \times 2$ factorial mating (Figure 4) strategy has been incorporated into the conventional hatchery program to increase effective population size and maintain genetic diversity (Busack and Knudsen 2007). Milt from a secondary male was added as a backup after 30 seconds. Actual fertilization takes place in a few seconds, so the backup male is not likely to contribute substantially to each individual egg lot unless semen from the primary male is non-viable.

## $\underline{2 \times 2 \text { Mating Cross }}$

Figure 4. Diagram of the $2 \times 2$ mating scheme used by WDFW in the conventional hatchery and captive program. All progeny in this diagram are defined as a family group.

Because of the mating strategy, some progeny from the two females are likely related as a family unit. Therefore, we consider all crosses with identical males (whether as primary or secondary to the mating) as one family unit to avoid within-family matings in the future. So while only 15 "family" units were chosen for the program, actual contribution of male and female parents (population size) to the captive program on a yearly basis has been higher. The actual number of parents that comprise the 1997-2002 BYs are given in Appendix A. Effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$ for each brood year was calculated by the formula:

$$
\mathrm{N}_{\mathrm{e}}=4\left(\mathrm{~N}_{\mathrm{M}}\right)\left(\mathrm{N}_{\mathrm{F}}\right) /\left(\mathrm{N}_{\mathrm{M}}+\mathrm{N}_{\mathrm{F}}\right)
$$

Where: $\mathrm{N}_{\mathrm{M}}=$ number of males
$\mathrm{N}_{\mathrm{F}}=$ number of females

The effective population sizes of the 1997-2002 BYs were $53,58,42,56,58$, and 59 , respectively. Allendorf and Ryman (1987) and Verspoor (1988) have suggested that little ( $<1 \%$ ) genetic variability will be lost in most salmonid species if the $\mathrm{N}_{\mathrm{e}}$ of the founding population is greater than 50 .

Selection of fry for the captive brood program was based on Bacterial Kidney Disease (BKD) screening of females, parent origin, and crosses (Appendix A). Screening for BKD, which is caused by the bacterium Renibacterium salmonirum, was a major factor in WDFW's decision to collect fry from the conventional hatchery program. By having the test results prior to selection, and by having rearing criteria that called for minimal sampling/handling, we felt that BKD outbreaks would be minimized. Spawned females were examined for BKD using the Enzyme Linked Immunosorbent Assay (ELISA) technique. Only females that were categorized as "Low" (0.11-0.19 Optical Density (OD)) or "Below Low" ( $<0.11$ OD) ELISA result were selected, with priority given to "Below Low" females. Priority for selection (in the following order) of fry was given to Natural x Natural, Natural x Hatchery (Mixed), and Hatchery x Hatchery crosses. All BYs identified for the program followed the same criteria.

Eighty fish from each of the 15 "family units" were selected (1,200 total fish) from each BY and each family group was moved to an individual $1.2-\mathrm{m}$ circular fiberglass tanks. After rearing for one year, each of the "family" groups was reduced to 30 fish/family ( 450 fish/BY) by random selection just prior to tagging. Excess fish were returned to the conventional hatchery production group. Fish destined for the captive program were tagged by "family" group with a CWT in the snout and adipose fin (backup). This was to verify "family" groups during future spawning activities so that full or half-siblings were not mated together. In addition to the CWT, an alphanumeric visual implant (VI) tag was placed behind the left or right eye to identify each fish. The VI tag, when it was retained, provided a quicker external "family" identification method than the CWT. In addition, fish that retained the VI would provide individual growth rates. After the fish were tagged, they were transferred to one of the $6.1-\mathrm{m}$ circular fiberglass tanks for rearing to maturity. Once the fish were transferred to the larger rearing tanks, they were not moved again unless survival rates were greater than anticipated, or density limits were exceeded within the rearing tanks. At maturity, fish were transferred to the adult raceway located in the spawning building. Family size and tagging procedures were the same for all brood years collected.

Density limits for each rearing tank were established prior to any stocking of fish. Most of the density limits prescribed were taken from the WDFW Dungeness River Captive Broodstock Program, where similar size starter and adult rearing tanks were used. Based on those density limits and expected survival and maturation rates, we were able to design the facilities needed. The current fish number maximums are as follows: $1.2-\mathrm{m}$ circular tanks $=$ no more than 200 fish/tank at age-1; 6.1-m circular tanks = no more than 150 fish/tank at age- 3 , or 100 fish/tank at age-4. Fish from each captive year were kept for a maximum of five years. If the fish did not spawn after that time it was killed outright and removed from the captive population.

Fry from each brood year were collected as described above, with appropriate families chosen for the program (Appendix A). Data on average length (mm), weight (g), and condition factor $(\mathrm{K})$ for each "family" group were compiled during tagging (Appendix B).

# Hatchery Rearing and Spawning 

## Captive Broodstock Rearing

Captive fish were reared at LFH using standard fish culture practices and approved theraputants in pathogen free well water that is a constant $11^{\circ} \mathrm{C}$. Each $6.1-\mathrm{m}$ circular captive tank was supplied with about $581 \mathrm{~L} / \mathrm{min}$ water flow, while the $1.2-\mathrm{m}$ tanks received about $23 \mathrm{~L} / \mathrm{min}$. To reduce the risk of catastrophic fish loss due to hatchery facility or operational failure, a number of safeguards were in place. LFH is staffed full time by personnel living on-station, providing for the protection of fish from vandalism and predation. The hatchery is also equipped with back-up generators in the event of power outages. All staff are trained in proper fish handling, transport, rearing, biological sampling, and WDFW fish health maintenance procedures to minimize the risk of fish loss due to human error. All fish were handled, transported, and propagated in accordance with the WDFW Fish Health Manual (WDFW 1996) and Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) disease prevention and control standards to minimize loss due to disease. Sanitation procedures were employed to reduce the transfer and incidence of fish diseases, and to promote quality fish in accordance with PNFHPC (1989) and Integrated Hatcheries Operations Team (Peck 1993) guidelines.

A variety of high quality commercial feed was provided through a state contract, and feed size varied with the estimated fish size of the different BYs. We have used Moore-Clark Nutra, Moore-Clark Fry, Bio-Products Salmon Brood Feed, and Moore-Clark Pedigree Trout Brood Feed on the captives. Estimated size only was generally used to prescribe feeding rates, as WDFW decided initially that too much handling of the fish to determine growth and size would jeopardize fish health. This decision resulted from problems that Oregon Department of Fish and Wildlife (ODFW) and Idaho Department of Fish and Game (IDFG) captive programs experienced during their first years of operation with monthly fish sampling. Due to the degree of early maturation of females in the 1997 and 1998 brood years, size-at-age recommendations were revised to produce more mature age-4 and 5 fish. Size-at-age goals were: age-1, 20-25 g; age- $2,150-200 \mathrm{~g}$; age- $3,900 \mathrm{~g}$; and age-4, 4,000 g. Daily satiation feeding was incorporated to obtain a larger size of adults at maturation. All captive fish were reared outside under natural photoperiod conditions. However, each of the $6.1-\mathrm{m}$ circular tanks was covered with camouflage netting to provide shade and lessen stress on the adults. The netting also prevented fish from jumping out of the tank. The ponds were cleaned weekly by lowering the water column and brooming the sides and bottom of the tanks.

During late June to early July, captive fish that were age-2 or greater were examined for signs of sexual maturation. Maturation was determined by a darkening in body coloration, as other morphological sexual characteristics were not as obvious. Mature female captives were injected with Erythromycin ( 20 mg per kg of body weight) at sorting to prevent Bacterial Kidney Disease. The broodstock were also treated with a formalin flush ( 167 ppm ) every other day to control fungus (Saprolegnia sp.). Mature captives were transported to broodstock holding raceways in common with, but separated by screens from broodstock (hatchery and naturalorigin) collected from the Tucannon River. Immature fish not transported to the spawning building were also treated with formalin for two weeks after handling to prevent a fungus outbreak.

## Captive Broodstock Spawning

Fish were anesthetized with MS-222 (tricaine methanesulfonate) and examined weekly for ripeness during the spawning season (late August to early October). Ripe females were killed and the eggs excised and collected into numbered plastic buckets. Milt from males was collected into numbered plastic bags, oxygenated, and stored on an insulated layer of ice until used for fertilization.

Using the same spawning matrix as described earlier (Figure 4), the eggs of two females were split in half and fertilized by two males following a $2 \times 2$ factorial spawning matrix approach. Milt from a secondary male was added as backup after 30 seconds to help ensure maximum fertilization. Mature fish (primarily age-2 jacks) not used for spawning were sacrificed at the end of the spawning season. Unlike other captive brood programs (e.g., Oregon Grande Ronde), cryopreservation of milt has not been employed as part of the program because obtaining enough males to spawn with mature females was never a problem.

Data collected from spawned fish included VIE identification number or CWT, fork length, postorbital to hypural-plate ( POH ) length, weight (from 2001 on), and tissue samples for DNA analysis.

The fertilized eggs were recombined and placed into iso-buckets, one female per bucket, and disinfected in an iodophore bath at the standard rate of 100 ppm for one hour. At the end of disinfection the water was turned on to $1.94 \mathrm{~L} /$ minute for each bucket. The eggs were treated every other day with formalin at $1,667 \mathrm{ppm}(37 \%$ formaldehyde) for 15 minutes for fungus control. Eggs were left untouched until they reached the eyed egg stage (approximately 580-600 temperature units (TUs)). At this time eggs were shocked and the following day the dead eggs were removed and enumerated. A sample of 100 live eggs was weighed and then all eggs were weighed with the mean weight per egg (egg size) applied to derive total number of live eggs. This estimate was decreased by $4 \%$ to compensate for water adherence to the eggs (WDFW Snake River Lab, unpublished data). The live and dead egg totals were combined to estimate total fecundity. The live eggs were moved into the vertical incubators for development and hatching. Water flow in the vertical tray incubators was set at $13.56 \mathrm{~L} /$ minute. When the alevins had fully absorbed their yolk they were moved to outside raceways ( $3 \mathrm{~m} \times 27 \mathrm{~m} \times 1.1 \mathrm{~m}$ ) at LFH for rearing.

## Captive Broodstock Progeny Rearing

## Lyons Ferry Hatchery

The fry were ponded and fed Bio-Diet Starter \#3, 6-8 times per day, seven days a week for the first two weeks. When fish were approximately 0.91 g they were treated with Erythromycin medicated feed for 28 days for the prevention of BKD. The feed was eventually changed to BioDiet Grower increasing from 1.0 mm to 2.5 mm according to the size of the fish.

Once they were feeding actively the protocol was to feed to satiation daily until they reached 1.5$2.3 \mathrm{~g} / \mathrm{fish}$. The feeding rates and number of days fed was then reduced so that growth would be
according to program requirements. To maintain a healthy environment, fish losses were removed and the screens broomed daily. The pond bottoms were vacuumed weekly.

In September, at approximately $13 \mathrm{~g} /$ fish, all captive progeny smolts were marked differently from conventional hatchery progeny for identification upon adult return. Captive smolts were unclipped and tagged with an agency-only wire tag (2000-2002 BYs) or CWT in the snout (production fish have an elastomer tag and CWT). When conventional hatchery or captive fish return as adults at the TFH adult trap, each unmarked (no adipose clip) adult Chinook will be scanned for wire in the snout and examined for a VIE tag. If the fish is not adipose fin clipped, and wire is present in the snout and no VIE is present, the fish is likely from the captive program. After tagging, the fish were held for at least two weeks before they were transferred to the TFH for final rearing.

## Tucannon Fish Hatchery

The TFH is supplied with three different water sources. River water is captured from the Tucannon River and ranges in temperatures from $0.6-15.6^{\circ} \mathrm{C}$ during use by the hatchery. The intake is located 0.81 km upstream of the hatchery. Water from the intake travels down an open channel into Rainbow Lake. Rainbow Lake functions as a reservoir to provide the hatchery with cooler water in the summer months and warmer water in the winter months. It also provides a pool of water to draw from when encountering adverse intake conditions, resulting in temporary loss of water flows. The water right for this source is $453 \mathrm{~L} / \mathrm{sec}$. From the outlet of Rainbow Lake the water travels through a 45.7 cm above ground pipeline to the hatchery. Well water is pumped from two separate sources to an aeration tower, and then gravity fed to the rearing units and the domestic pump building. The combined well water right is $56.6 \mathrm{~L} / \mathrm{sec}$, with well \#2 running between $12.2-13.9^{\circ} \mathrm{C}$ and well $\# 3$ running a constant $16.1^{\circ} \mathrm{C}$. Spring water is pumped from an underground collection site to the same aeration tower and gravity fed to the rearing units. The water right for this source is $150 \mathrm{~L} / \mathrm{sec}$, and has a stable temperature of $10.6-11.1^{\circ} \mathrm{C}$.

The vessels used for rearing the captive progeny at TFH were three concrete round ponds approximately 12.2 m in diameter with a maximum of $79.8 \mathrm{~m}^{3}$ of rearing area each, two concrete $3.1 \times 24.4 \times 0.9 \mathrm{~m}$ raceways, and one concrete $4.6 \times 41.5 \times 1.5 \mathrm{~m}$ raceway. The number and size of vessels used was dependent on the total number on hand for each release year.

Curl Lake AP is located along the Tucannon River 8 km upstream of the Tucannon Hatchery. It is an earthen pond holding approximately $23,520 \mathrm{~m}^{3}$ of water. It has a water right of $169.9 \mathrm{~L} / \mathrm{sec}$ and is supplied with water from the Tucannon River through a gravity water supply system. Water temperatures during the acclimation period range from $1.1-8.9^{\circ} \mathrm{C}$.

## Pond Densities

The WDFW Fish Health Specialist has established pond density guidelines for Chinook. The suggested maximum density index (DI) for Chinook is $1.25 \mathrm{~kg} / \mathrm{m}^{3} / \mathrm{cm}$. Fish reared above the density index are at a greater risk of disease.

The number of juveniles being transferred from LFH each year would determine which rearing vessels would be utilized to keep the DI level as low as possible. The average loading DI upon
receiving fish was $0.52 \mathrm{~kg} / \mathrm{m}^{3} / \mathrm{cm}$. The fish were reared for approximately four months at the TFH. Prior to transfer to Curl Lake AP, the highest DI averaged $0.64 \mathrm{~kg} / \mathrm{m}^{3} / \mathrm{cm}$.

## Feed

For the 2000-2004 brood years, once the captive progeny juveniles were transferred to the TFH they were fed a Bio Moist Feed. This diet had $20 \%$ moisture content. Because of estimated size target goals at transfer to Curl Lake AP, precocial male concerns, rearing timeframe, and proven palatability with Chinook, we thought this would be the best diet to use. Once the fish were transferred to Curl Lake AP they were fed Clarks dry diet since food is delivered with the use of a blower feeder that does not work well with moist feeds. For the 2005-2006 brood years, due to the discontinuation by the manufacturer of the Bio Moist Feed, fish were fed the Clarks fry diet from arrival at the TFH and at Curl Lake AP. Feed conversion rates averaged 0.75 kg fed to 0.45 kg flesh gain at the TFH. Food conversion averaged 0.29 kg feed fed to 0.45 kg flesh gain at Curl Lake AP.

Water

At the TFH, juveniles were reared on surface water as long as the temperatures stayed above $3^{\circ}$ C. In the mid 1990s the conventional hatchery fish had been identified having low levels of Erythrocytic Inclusion Body Syndrome (EIBS) virus. EIBS causes severe anemia and the length of infection is temperature dependent, with shorter durations at higher temperatures. The recommendation of the WDFW Fish Health Specialist was to turn on a mixture of well/spring water with the river water in the winter months to keep it close to $4.4^{\circ} \mathrm{C}$. This would allow the fish's immune system to aid fighting off the virus. This procedure has been applied during the rearing of Chinook salmon ever since. Typically mid-December through late January is when well and spring water is mixed with river water to keep the temperatures at a desired level. Once the fish have been moved up to Curl Lake AP they are reared exclusively on surface river water.

## Target Sizes

For the 2000-2004 brood years, the plan was to mimic the size at release goal of the conventional supplementation fish at 30 g . The target size at transfer to Curl Lake AP from TFH in February of each year was 25 g to project a release size of 30 g . For the 2005-2006 brood years, the release goal was changed to a release size of 50 g from Curl Lake AP in an attempt to increase survival and return rates. The target size at transfer to Curl Lake AP for 50 g fish from TFH was $35-38 \mathrm{~g}$ for those two brood years.

## Health of Captive Broodstock

Overall survival of the captive fish was good with mortality of immature fish from age-1 to maturation for the five brood years ranging from $3.2 \%$ to $16.9 \%$ (Table 1; Appendix C). The 1997 brood year experienced the highest mortality due to external fungus following sorting. With subsequent brood years, formalin treatments were initiated immediately following handling and mortality was substantially reduced.

Table 1. Total mortalities of immature fish from ages one to five prior to maturation of the Tucannon River spring Chinook captive broodstock at Lyons Ferry Hatchery.

|  | Number at | Mortality |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Brood Year | Age 1 | Male | Female | Total | Percent |
| 1997 | 433 | 22 | 51 | 73 | 16.9 |
| 1998 | 438 | 13 | 18 | 31 | 7.1 |
| 1999 | 409 | 7 | 6 | 13 | 3.2 |
| 2000 | 450 | 6 | 12 | 18 | 4.0 |
| 2001 | 450 | 10 | 21 | 31 | 6.9 |

BKD was not observed in the captives, thus supporting the selection criteria used in founding. Also, BKD-ELISA testing of female captives at spawning also showed that the captive brood was not infected (Table 2).

Table 2. BKD-ELISA testing of female Tucannon River spring Chinook captive broodstock at Lyons Ferry Hatchery.

## Health of Captive Broodstock Progeny

Most brood years of Tucannon River Chinook captive progeny were healthy throughout their rearing at LFH and TFH and upon release. The only exception was the 2001 brood year. Bacterial kidney disease was diagnosed for that brood year in November 2002 and chronic mortality continued throughout the rearing cycle. The fish were treated with erythromycin medicated feed and mortality declined following treatment. The 2001 brood year Chinook could have been infected horizontally by the use of the river water supply at the TFH, or by crossinfection from spring or fall Chinook at LFH.

## Monitoring and Evaluation

## Background

As previously mentioned, the LSRCP Tucannon River Chinook conventional hatchery program performed ongoing evaluations of the natural, conventional hatchery, and captive populations during the captive program. Some of the monitoring and evaluation activities include or have included: smolt release sampling, smolt trapping, spawning ground surveys, genetic monitoring, snorkel surveys for juvenile population estimates, spawning, fecundity monitoring, and experimental release strategies for smolts. Through these and other activities, survival rates of the natural, conventional hatchery, and captive origin fish have been documented. These and other activities will continue to play a major role in evaluating the captive program in the future (for both parents and progeny) and determine the program's success or failure. The last captive progeny are expected to return in 2011. The following are the results through 2008.

## Statistical analysis

Analysis of variance (ANOVA) was used to test for significant differences among the means for data with normal distributions. Percent data was arcsine transformed for normality prior to analysis (Zar 1996). Multiple range tests were then used to determine which means were significantly different. A nonparametric Kruskal-Wallis test was employed to test for significant differences among multiple medians for data sets with nonnormal distributions. Notched box-and-whisker plots were then used to determine which individual medians were statistically different from each other. If two notches for any pair of medians overlap, there is not a statistically significant difference between those two medians. If the two notches for any pair of medians do not overlap, there is a statistically significant difference between the medians. All statistical tests were performed at the $95 \%$ confidence level.

## Spawn Timing

Spawn timing of natural, conventional hatchery, and captive origin fish was followed through the duration of the captive program. Captive female spawn timing was generally two weeks later than natural and hatchery origin fish collected from the Tucannon River (Figure 5). Mature captives were held upstream of broodstock collected from the river in 2003 to address possible disease concerns, however, spawn timing appeared to be adversely affected (Gallinat 2004). For the rest of the program's duration, mature captives were held downstream of fish collected from the river.

Figure 5. Mean spawn timing comparison of natural, conventional hatchery, and captive (C.B) origin ripe females for the 2000-2006 spawning years.

Although the captive fish were reared outdoors under natural photoperiod conditions, the water temperature does not fluctuate as it does in nature and remains a constant $11^{\circ} \mathrm{C}$ due to the use of well water at LFH. Feed levels in the hatchery environment also do not vary as they would in nature. Although spawn timing was about two weeks later, we were able to spawn captive females with natural and hatchery-origin males during the beginning of each spawning season (Table 3).

Table 3. Number of viable captive females and natural-origin, conventional hatchery, and captive males that were spawned during the captive program. (Some natural-origin males were spawned more than once.)

| Spawn <br> Year | Captive <br> Females $^{\text {a }}$ | Natural <br> Males | Hatchery <br> Males | Captive <br> Males | Total <br> Parents |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 12 | 5 | 0 | 8 | 25 |
| 2001 | 166 | 23 | 0 | 83 | 272 |

| 2006 | 86 | 17 | 24 | 0 | 127 |

[^1]
## Age Composition

Both male and female Chinook that reared in the hatchery environment for the captive program matured and spawned at younger ages than conventional hatchery and natural-origin fish (Figure 6). The majority of captive males matured at age- 3 compared to age- 4 for conventional hatchery and natural origin males collected from the river (Figure 6).

Figure 6. Age composition at maturity for male and female captive, conventional hatchery, and natural origin Tucannon River spring Chinook.

The majority of females from all origins matured at age-4 with captive spawners having few age5 females in the spawning population (Figure 6). This suggests there is a strong environmental component to maturity at age. The hatchery environment, with warmer water temperatures and abundant food supply, allows for faster growth that results in earlier maturation. Larsen et al. (2006) found they could adjust the precocity rate of male hatchery-reared salmon by modulating growth during certain times of the year. This method could possibly be employed to reduce the amount of early maturation in captive programs.

## Age-4 Female Comparisons

Age-4 females were the dominant age class for all three populations. Hence, we focused comparisons of reproductive traits on females from this age group.

## Fork Length

Mean fork length of age-4 captive brood females spawned from 2001-2006 was 53 cm compared to 69 and 71 cm for age- 4 conventional hatchery and natural origin females, respectively. There was a statistically significant difference amongst the medians for all three groups at the $95 \%$ confidence level (Figure 7).

Figure 7. Notched box-and-whisker plots of fork length (cm) for age-4 captive, conventional hatchery, and natural origin spawned females, 2001-2006.

## Egg Size and Eye-up Mortality

Mean egg size of age- 4 captive fish was $0.256 \mathrm{~g} / \mathrm{egg}$ compared to mean egg sizes of 0.234 and $0.230 \mathrm{~g} / \mathrm{egg}$ for age- 4 conventional hatchery and natural origin females, respectively. There was
a statistically significant difference $(P<0.05)$ between median egg size of the captives and the median egg size of conventional hatchery and natural origin fish (Figure 8).

Figure 8. Notched box-and-whisker plots of egg size (g) for age-4 captive, conventional hatchery, and natural origin spawned females, 2001-2006.

Despite their smaller size on average, age-4 captive females had significantly larger eggs. This contradicts a study in British Columbia on farmed Chinook salmon by Heath et al. (2003), who found that hatchery rearing relaxes natural selection favoring large eggs, allowing fecundity selection to drive rapid evolution of small eggs. They stated that these small eggs could lead to reduced survival and limit the success of hatchery programs. However, Beacham (2003) points out that Heath and his colleagues incorrectly attributed an ocean environmental effect and female variation on egg size to a genetic change as a result of hatchery enhancement. The broodstock they studied was also developed to satisfy a niche market and matures at a much smaller size and has unusually small eggs (Beacham and Murray 1993; Beacham 2003). It was also not clear if the British Columbia hatchery incorporated wild broodstock into their captive commercial hatchery population.

In an earlier work, Heath et al. (1999) found egg size was positively correlated with early survival, but negatively correlated with fecundity. Kinnison et al (2001) also found that egg size is strongly correlated with initial offspring (fry) size in salmonids and offspring size is in turn correlated with survival in salmon. They found that a proportionate increase (or decrease) in fry size results in more than an equivalent change in fry-to-adult survival. Heath et al. (1999) however, found that progeny hatched from small eggs grew faster than progeny hatched from large eggs. If this were true, then any survival advantage there was for investing energy into large eggs could be nullified by producing a greater number of smaller eggs. Large egg size did not appear to increase survival in our study since mortality to eye-up was $49 \%$ for captive brood eggs, compared to eye-up mortalities of $4 \%$ and $3 \%$ for conventional hatchery and natural origin
fish, respectively. Quality of sperm was determined not to be a factor in the mortality of eggs (Gallinat 2006). The high egg mortality for captive fish may be related to unknown environmental, physiological, or dietary factors.

Tucannon River Chinook migrate 622 kilometers from the mouth of the Columbia River to the mouth of the Tucannon River (Stein 1998). This long migration may help explain the difference in egg size between the migrating natural and conventional hatchery fish and the non-migrating captive salmon. Beacham and Murray (1993) and Healey (2001) suggested that a limited amount of energy could be expended on egg production on more northern stocks and stocks with long freshwater migrations. Kinnison et al. (2001) also concluded that migration in salmon not only cost the fish in energy reserves, but was also expressed as a cost to ovarian investment, primarily in egg size. Thus, captive fish may be able to reallocate more energy into producing larger eggs due to a readily available food supply and the fact they are non-migratory during the maturation period.

## Fecundity

For captives, the large egg size in small fish resulted in very low fecundity compared to conventional hatchery and natural origin fish collected from the Tucannon River. Mean fecundity of age- 4 captive brood females was 1,664 eggs/female compared to age- 4 conventional hatchery $(2,952)$ and natural origin $(3,381)$ females spawned from 2001-2006. There was a statistically significant difference $(P<0.05)$ among median fecundities for all three groups of fish (Figure 9).

Figure 9. Notched box-and-whisker plots of fecundity for age-4 captive, conventional hatchery, and natural origin spawned females, 2001-2006.

## Relative Fecundity

Relative fecundity was used to correct for the effect of body size on the number of eggs produced by each female. Relative fecundity was calculated by dividing total fecundity by body weight ( kg ), since given fish of equal length, the fish with the larger girth could potentially hold more eggs.

Mean relative fecundity of age- 4 captive fish was $779 \mathrm{eggs} / \mathrm{kg}$ and was lower compared to the relative fecundities of 836 and 881 eggs $/ \mathrm{kg}$ for age- 4 conventional hatchery and natural origin females, respectively. There was a statistically significant difference $(P<0.05)$ among the median relative fecundities for all three groups of fish (Figure 10).

Figure 10. Notched box-and-whisker plots of relative fecundity for age-4 captive, conventional hatchery, and natural origin spawned females, 2001-2006.

## Reproductive Mass

Female salmon may allocate similar amounts of reproductive effort but partition it differently (e.g., small eggs and high fecundity may be equal in energy expenditure to large eggs and low fecundity). In order to account for differences in fecundity caused by egg size, reproductive mass was calculated by multiplying fecundity by egg size to provide total reproductive contribution in grams.

Mean reproductive mass of age-4 captive brood females was 426 g and was considerably lower compared to the mean reproductive mass of conventional hatchery ( 689 g ) and natural ( 778 g ) origin females. There was a statistically significant difference ( $P<0.05$ ) among the median
reproductive mass of the captives and the median reproductive mass of conventional hatchery and natural origin fish (Figure 11).

Figure 11. Notched box-and-whisker plots of reproductive mass for age-4 captive, conventional hatchery, and natural origin spawned females, 2001-2006.

## Adult Outplants

During 2002, based on the number of mature captive adults available, it was estimated that we would likely be in excess of our approved release goal of 150,000 smolts. To stay within the allowed release goal, WDFW decided to release excess mature captives into the Tucannon River just prior to spawning. On 20 August 2002, 97 (21 1998 BY and 761999 BY) excess adults were released into the Tucannon River at Panjab Bridge (rkm 74.5). All released fish were tagged with metal (Monel) jaw tags and radio transmitters were inserted into ten of the larger (presumably female) fish for tracking and monitoring in the wild. Radio tagged fish were monitored weekly through the end of September (Appendix D). Table 4 summarizes the tagging and recovery information from the radio tagged fish. Two of the radio tagged females spawned successfully within 2 km of the release site (9/165 and 9/192). Another female (9/167) that was attempting to spawn (actively digging a redd) died after releasing less than $10 \%$ of her eggs. Of the remaining seven fish: three tags were recovered on the stream bank without a carcass and may have been illegally harvested; two fish were eaten by predators; one fish was a prespawn mortality unrecoverable in a debris jam; and one fish (9/203) was never located after release the radio stopped transmitting or the fish and transmitter left the area.

Table 4. Radio tagging and recovery data for ten adult captive Chinook tagged on 16 July and released on 20 August at Panjab Bridge in the Tucannon River during 2002.

|  | Release Data |  | Recovery Data |  |  |  |  |

Outplanted adults differed from natural and hatchery-origin fish in the river in morphology and coloration. Captive males lacked a prominent kype and captive fish were more golden-yellow in color. During redd surveys, released captive adults were observed being chased by more dominant male and female natural and hatchery-origin fish in the river.

In studies by Berejikian et al. (1997), wild coho females produced more nests than captive females. They also found that captive coho males were dominated by wild males and were also attacked more often by females than wild males. Fleming and Gross (1993) found coho hatchery females were delayed in spawning, retained more eggs, spawned in less desirable areas, and were less successful in guarding nest sites.

Losses to predation may be higher for fish released from a hatchery environment due to inability to accurately assess predation risks, secondary stress effects, and a general unfamiliarity with their new surroundings (Steward and Bjornn 1990).

Due to the low frequency of natural spawning by released fish, high mortality due to predation and presumed illegal harvest, and higher egg mortality in the hatchery during 2002 than predicted, the priority for excess fish was changed. The co-managers agreed to spawn the excess adults and release their progeny as parr.

## Juvenile Releases

Number of parr and smolts released from the captive broodstock program is provided in Appendix E. The captive program provided a boost in the number of smolts released that otherwise would not have occurred had the program not been in place (Figure 12).

Figure 12. Number of captive progeny and conventional hatchery smolts released by year (1987-2008).

## PIT Tagging

We used passive integrated transponder (PIT) tags to compare emigration travel timing and relative success of the captive progeny with our conventional hatchery fish for the 2001-2006 brood years. Due to the small number of captive progeny released, the 2000 brood year was not PIT tagged for comparisons with the conventional hatchery fish. The goal for each brood year was to tag 1,000 captive progeny and 1,000 conventional hatchery fish during early February before transferring them to Curl Lake AP for acclimation and volitional release (Appendix F). Mortalities after tagging were low, although some minor delayed mortality may have occurred after transfer. Detection rates at Snake and Columbia river dams were always higher for conventional hatchery fish compared to captive progeny but differences were not significant, with the exception of the 2006 brood year (Appendix F). The difference may be sample size related for the 2006 brood year.

Survival probabilities were estimated by the Cormack Jolly-Seber methodology using the Survival Under Proportional Hazards (SURPH) 2.2 computer model. The data files were created using the PitPro version 4.1 computer program to translate raw PIT Tag Information System (PTAGIS) data of the Pacific States Marine Fisheries Commission into usable capture histories for the SURPH program. As with the total detection rates, survival probabilities were always higher for the conventional hatchery fish compared to the captive progeny (Table 5). With the exception of the 2006 brood year, differences were not significant ( $P>0.05$ ). Since both groups were raised in the same manner and released at similar sizes, differences may be related to hatchery domestication effects or other unknown factors.

Table 5. Survival probabilities from Curl Lake Acclimation Pond (rkm 65.6) to Lower Monumental Dam for conventional hatchery and captive progeny Tucannon River spring Chinook salmon for the 2001-2006 brood years.

| Brood <br> Year | Origin | Number <br> Tagged | Survival <br> Probability | S.E. |

## Survival Rates

Point estimates of population sizes have been calculated for various life stages (Appendix G) of natural, conventional hatchery and captive origin fish based on fecundity estimates, hatchery records, smolt trapping and redd surveys. From these data, survivals between life stages have been calculated to assist in evaluation of the captive program (Table 6).

Table 6. Percent survival by life stage of progeny from naturally reared, conventional hatchery reared, and captive reared Tucannon River spring Chinook salmon for the 2000-2006 brood years.

|  |  | Natural |  |  | Conventional Hatchery |  |  | Captive Brood |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Brood | Egg to | Parr to | Egg to | Egg to | Parr to | Egg to | Egg to | Parr to | Egg to |  |
| Year | Parr | Smolt | Smolt | Parr | Smolt | Smolt | Parr | Smolt | Smolt |  |
| 2000 | 13.8 | 44.9 | 6.2 | 95.6 | 82.8 | 79.2 | 29.7 | 70.7 | 21.0 |  |
| 2001 | 6.1 | 60.1 | 3.6 | 95.0 | 84.0 | 79.8 | 69.4 | 71.9 | 49.9 |  |
| 2002 | 6.7 | 83.8 | 5.7 | 89.5 | 81.6 | 73.0 | 28.6 | 88.7 | 25.4 |  |
| 2003 | 9.1 | 56.2 | 5.1 | 89.9 | 56.3 | 50.6 | 53.3 | 78.9 | 42.0 |  |
| 2004 | 6.0 | 68.3 | 4.1 | 91.8 | 52.4 | 48.1 | 45.3 | 93.9 | 42.6 |  |
| 2005 | 5.8 | 83.1 | 4.8 | 93.9 | 98.7 | 92.6 | 35.9 | 95.8 | 34.4 |  |
| 2006 | -- a $^{\text {a }}$ | -- - $^{\text {a }}$ | 10.7 | 90.9 | 94.8 | 86.2 | 48.8 | 98.4 | 48.0 |  |
| Mean | 7.9 | 66.1 | 5.7 | 92.4 | 78.6 | 72.8 | 44.4 | 85.5 | 37.6 |  |
| S.D. | 3.1 | 15.4 | 2.3 | 2.5 | 17.8 | 17.2 | 14.5 | 11.6 | 11.1 |  |

${ }^{\text {a }}$ A snorkel survey was not performed to allow an estimate of parr for the 2006 brood.
Egg-to-parr survival for captive progeny averaged 44.4\% over seven years (Table 6). This is higher than the $7.9 \%$ egg-to-parr survival estimated for in-river natural-origin Tucannon River Chinook due to their protection in the hatchery environment, but was significantly $(P<0.05)$ less than the $92.4 \%$ survival from the conventional hatchery fish. Parr-to-smolt survival averaged $85.5 \%$ for the captive brood progeny and was not significantly different $(P>0.05)$ from natural origin and conventional hatchery fish. Egg-to-smolt survival was $37.6 \%$ for the captive fish and was significantly $(P<0.05)$ higher than natural-origin fish (5.7\%) but significantly $(P<0.05)$ lower than conventional hatchery-origin fish (72.8\%).

Smolt-to-adult survival for captive progeny has averaged $0.02 \%$ for the first five years of the program (Table 7) and was significantly $(P<0.05)$ less than the SARs of $0.13 \%$ and $1.07 \%$ for conventional hatchery and natural-origin fish, respectively. Due to the very poor adult returns of the captive progeny from earlier releases, size at release was increased to $50 \mathrm{~g} /$ fish beginning with the 2005 brood year in an attempt to increase juvenile survival and return more adults back to the Tucannon River (Table 7).

Table 7. Comparisons of adult returns and smolt-to-adult (SAR) returns of natural, conventional hatchery, and captive origin Tucannon River spring Chinook salmon for the 2000-2005 brood years (2004 and 2005 incomplete returns).

| 2005 | 90,056 | 158 | --- |  | 0.18 | --- |
| Mean |  |  |  |  | 0.05 | 0.02 |

Based on adult returns from the 2000-2005 broods, captives produced only 0.17 adults for every spawner, which was significantly $(P<0.05)$ lower than naturally reared salmon that produced 0.67 adults for every spawner (Table 8). Conventional hatchery reared fish produced 1.66 adults per spawner and was the only group above replacement levels.

While the captive progeny will continue to return until 2011, based on results to date, the Tucannon River Chinook captive program has been unsuccessful in almost every year in meeting the adult return goals of the program. We are cautiously optimistic that the change in size at release beginning with the 2005 brood year will increase SAR survival and improve adult returns for the final years of the program.

## Termination of the Program

While the Tucannon River Chinook captive program did produce additional smolts for release, the program has performed poorly to date compared with our conventional hatchery supplementation program. Captive programs of Pacific salmon have been plagued with high mortality rates, inappropriate spawn timing, precocious maturation of males, low egg viability, and captive adults that are smaller than wild fish (Flagg and Mahnaken 1995; Schiewe et al. 1997). The Tucannon River spring Chinook captive broodstock program was ended because of the following reasons:

- The program had a specific endpoint from the beginning as it was designed to last for only one generation (five brood years).
- Success of the program did not meet our goals and did not match or enhance the conventional hatchery supplementation program.
- WDFW has concerns about continued severe hatchery intervention and long-term effects on the population.
- Natural production/adults increased regardless of the lack of adult returns from the captive program (Figure 13).

Figure 13. Total estimated escapement for Tucannon River spring Chinook salmon for the 1985-2008 run years.

## Conclusions and Recommendations

The WDFW LSRCP evaluation program will continue to document returning adults from the captive program and compare their survival to survivals from the conventional hatchery program and natural origin fish. The major conclusions and recommendations for the Tucannon captive program are as follows:

- Selecting fry from parents based on Bacterial Kidney Disease (BKD) screening benefited the program, as BKD was not a problem with the Tucannon captives unlike other captive programs that collect eggs/fry from the wild.
- Size of the captive adults were significantly smaller than conventional hatchery and natural origin adults and egg quality was poor with high egg mortality. This may be due to unknown environmental, physiological, or dietary factors. More research should be conducted on the nutrition and growth requirements of Chinook salmon that are captively reared.
- By selecting fry from the conventional hatchery program, effective population size of the Tucannon River Chinook salmon broodstock was generally above 50 without removing additional fish from the river.
- The captive program did provide additional smolts for release that otherwise would not have been produced without the program.
- The release of excess captive adults into the natural environment to spawn on their own is not recommended as the fish are raised in a protected hatchery environment and appear to lack the necessary skills to survive in the wild.
- Adult returns from the program to date have been poor in comparison to the conventional hatchery program and have failed to return the 300 adults expected per year. It is unknown whether hatchery domestication effects or other unknown factors have played a role in the poor returns, as the captive progeny and conventional hatchery fish are reared and released in the same manner. Captive progeny size at release was increased from 30 g /fish to 50 g /fish for the 2005 and 2006 brood years and we are cautiously optimistic this change will increase SAR survival.
- Because of the small size, low fecundity, and poor egg quality from the captive adults, and poor returns of captive progeny, the co-managers decided to increase the release goal of the conventional hatchery supplementation program from 132,000 to 225,000 yearling smolts instead of attempting to continue with the Tucannon River Chinook captive program.

${ }^{\text {a }}$ Total includes 3 fish of unknown sex. (Three died from family 2 during tagging)
${ }^{\mathrm{b}}$ Total includes 1 fish of unknown sex (just fish head found from Age 2).
${ }^{c}$ Total includes 7 fish from unknown families.

## APPENDIX D

Appendix D. Movements of ten radio tagged captive female adults released into the Tucannon River during 2002.

| Channel/Code Date | Tucannon rkm | Location | Comments |
| :---: | :---: | :---: | :---: |
| 9/165 |  |  |  |
| 7/16/02 |  | Lyons Ferry Hatchery | Length at tagging - 58.0 cm . |
| 8/20/02 | 74.5 | Panjab Bridge | Released into river. |
| 8/27/02 | 72.0 | $3{ }^{\text {rd }}$ Cattle guard |  |
| 8/30/02 | 73.0 | 100 m above C.C. Br. |  |
| 9/05/02 | 73.0 | 100 m above C.C. Br. | Drive by. |
| 9/09/02 | 72.8 | Below C.C. Bridge | Between campground and cattle guard. |
| 9/13/02 | 72.9 | Below C.C. Bridge | R.B. lower end of habitat site, by new redd. |
| 9/16/02 | 72.9 | Below C.C. Bridge | L.B. below rocks, with natural male. |
| 9/20/02 | 72.9 | Below C.C. Bridge | Area where she was digging now small T.D. |
| 9/23/02 | 72.9 | Below C.C. Bridge | Fungused eyes, fins, tail frayed. |
| 9/25/02 | 72.9 | Below C.C. Bridge | Recovered tag and fish, $100 \%$ spent. |
| 9/167 |  |  |  |
| 7/16/02 |  | Lyons Ferry Hatchery | Length at tagging - 55.5 cm . |
| 8/20/02 | 74.5 | Panjab Bridge | Released into river. |
| 8/27/02 | 73.2 | HMA5-S Side Channel |  |
| 8/30/02 | 73.3 | Log jam below log weir |  |
| 9/05/02 | 72.9 | Cow Camp Bridge | Drive by. |
| 9/09/02 | 73.0 | 100 m above C.C. Br. | By redd 2-6, with other fish, natural male close by. |
| 9/13/02 | 73.0 | 100 m above C.C. Br. | Recovered tag and fish - did not spawn. |
| 9/171 |  |  |  |
| 7/16/02 |  | Lyons Ferry Hatchery | Length at tagging - 56.5 cm . |
| 8/20/02 | 74.5 | Panjab Bridge | Released into river. |
| 8/27/02 | 73.2 | HMA5-S Side Channel |  |
| 8/30/02 | 73.2 | HMA5-S Side Channel |  |
| 9/05/02 | 73.2 | Between C.C. and C.G. 9 | Drive by. |
| 9/09/02 | 73.4 | Above C.C. Br. - 35 km | Log jam near 9/04/02JD test dig. |
| 9/13/02 | 74.5 | Below Panjab Ck. Mouth | Went down to pool with 9/183 then upstream. |
| 9/16/02 | 73.6 | C.G. 9 lower entrance | Drive by. |
| 9/20/02 | 73.6 | S.C. at C.G. 9 | Near new redds in S.C., not actively digging. |
| 9/23/02 | 73.4 | Log jam above rock sill | Recovered tag and fish. Fish partially eaten. |
| 9/179 |  |  |  |
| 7/16/02 |  | Lyons Ferry Hatchery | Length at tagging - 55.5 cm . |
| 8/20/02 | 74.5 | Panjab Bridge | Released into river. |
| 8/27/02 |  | Ladybug Flat? | Couldn't locate - heard chirps near Ladybug. |
| 8/30/02 |  | Not Found | Couldn't locate. |
| 9/05-9/02 | 77.7 | Ladybug Flat | Run and pool under poplar, fish moving around. |
| 9/13-16/02 | 77.7 | Ladybug Flat | Under alder, about 25 m upstream of path sign. |
| 9/20/02 | 77.7 | Ladybug Flat | Recovered tag only. Tag found between rocks. Possibly poached. |

Appendix D (continued). Movements of ten radio tagged captive female adults released into the Tucannon River during 2002.

| Channel/Code <br> Date | Tucannon rkm | Location | Comments |

${ }^{\text {a }}$ Total includes detections at Ice Harbor Dam.
Note: Mean travel times listed are from total number of fish detected at each dam, not unique recoveries for a tag code.
Abbreviations are as follows: LMJ - Lower Monumental Dam; MCJ - McNary Dam; JDJ - John Day Dam; BONN - Bonneville Dam; S.D. - Standard Deviation;
TD - Mean Travel Days.

## APPENDIX G

${ }^{\text {a }}$ Based on fully spawned females.
${ }^{\mathrm{b}}$ Incomplete brood year - adults still returning.
${ }^{\text {c }}$ Snorkel surveys not conducted.

This program receives Federal financial assistance from the U.S. Fish and Wildlife Service Title VI of the Civil Rights Act of 1964, Section 504 of the Rehabilitation Act of 1973, Title II of the Americans with Disabilities Act of 1990, the Age Discrimination Act of 1975, and Title IX of the Education Amendments of 1972. The U.S. Department of the Interior and its bureaus prohibit discrimination on the bases of race, color, national origin, age, disability and sex (in educational programs). If you believe that you have been discriminated against in any program, activity or facility, please write to:

U.S. Fish and Wildlife Service Office of External Programs 4040 N. Fairfax Drive, Suite 130<br>Arlington, VA 22203

[^0]:    ${ }^{1}$ From this point forward, the term "Chinook" refers to spring Chinook salmon unless otherwise noted.
    ${ }^{2}$ From this point forward, the term "captive" refers to any fish that was associated with the captive program at Lyons Ferry Hatchery.

[^1]:    ${ }^{\text {a }}$ Does not include females that were green/non-viable or spawned out and killed outright.

[^2]:    ${ }^{1}$ Low $=0.11-0.19$ Optical Density; Below Low $=<0.11$ Optical Density.

[^3]:    ${ }^{1}$ Low $=0.11-0.19$ Optical Density; Below Low $=<0.11$ Optical Density.
