## Acknowledgments

The Tucannon River Spring Chinook Salmon Hatchery Evaluation Program is the result of efforts by many individuals within the Washington Department of Fish and Wildlife (WDFW) and from other agencies.

We would like to express sincere gratitude to Butch Harty, Lyons Ferry Complex Manager, for his coordination efforts. We thank Hatchery Specialists Doug Maxey and Steve Jones for their cooperation with hatchery sampling, providing information regarding hatchery operations and hatchery records, and their input on evaluation and research activities. We also thank all additional hatchery personnel who provide the day-to-day care of the spring chinook and for their assistance with hatchery spawning, sampling, and record keeping.

We thank Lynn Anderson and the Coded-Wire Tag Lab staff for their assistance in coded-wire tag verification and Julie Hooff for tagging the supplementation and captive brood fish. We also thank John Sneva for reading scales, and Steve Roberts for providing information on fish health issues that arose during the year.

We thank the University of Idaho for providing data regarding their radio tagging studies on the Columbia and Snake rivers.

We thank Mark Schuck, Joe Bumgarner, Glen Mendel, Todd Pearsons, and Jim Scott for providing critical reviews of the draft report.

This project was funded by the United States Fish and Wildlife Service through the Lower Snake River Compensation Plan Office.

## Abstract

Lyons Ferry Hatchery (LFH) and Tucannon Fish Hatchery (TFH) were built/modified under the Lower Snake River Fish and Wildlife Compensation Plan. One objective was to compensate for the estimated annual loss of 1,152 spring chinook (Tucannon River stock) caused by hydroelectric projects on the Snake River. The standard supplementation production goal is 132,000 fish for release as yearlings at $30 \mathrm{~g} /$ fish or 15 fish per pound ( fpp ). The captive brood production goal is 150,000 yearlings at 30 g /fish. This report summarizes activities of the Washington Department of Fish and Wildlife Lower Snake River Hatchery Evaluation Program for Tucannon River spring chinook for the period April 2001 to April 2002.

Six hundred eighty-one fish were captured in the TFH trap in 2001 (404 natural adults, 1 natural jack, 181 hatchery adults, and 95 hatchery jacks); 106 were collected and hauled to LFH for broodstock and the remaining fish were passed upstream.

During 2001, all fish collected for broodstock were spawned. Prespawning mortality has been low since broodstock began being held at LFH in 1992, and is generally less than $10 \%$ each year.

Spawning in 2001 at LFH occurred between August 28 and September 18, with peak eggtake on September 11. A total of 184,127 eggs were collected. Egg mortality to eye-up was 2,225 eggs, with an additional loss of 6,698 sac-fry. Total fry ponded for production in the rearing ponds was 174,934 . One hundred twenty-five mature 1997 brood year females from the captive broodstock program were spawned in 2001. Mean fecundity was 1,990 eggs/female based on 105 fully spawned females; egg survival was $69 \%$. Forty-one mature 1998 brood year females were also spawned in 2001. Mean fecundity based on 39 fully spawned females was 1,160 eggs/female; egg survival was $81 \%$.

One wild male spring chinook salmon that was radio tagged at Bonneville Dam entered the Tucannon River in 2001. This fish had also been PIT tagged as a juvenile at the Tucannon River smolt trap. Growth rate from capture at the smolt trap to radio tagging at Bonneville Dam averaged $27.3 \mathrm{~mm} /$ month.

WDFW staff conducted spawning ground surveys in the Tucannon River between August 29 and October 3, 2001. One hundred sixty-eight redds and 112 carcasses were found above the adult trap and 130 redds and 114 carcasses were found below the trap in 2001 Based on annual redd counts, broodstock collection, and in-river pre-spawning mortalities, the estimated escapement for 2001 was 1,012 fish ( 892 adults and 120 jacks).

Length and weight samples were collected twice during the rearing cycle for 2000 BY juveniles at TFH and Curl Lake Acclimation Pond. All 2000 BY juveniles were marked in October at

LFH, transported to TFH, and transported again in February to Curl Lake for acclimation and volitional release during March and April.

Snorkel surveys were conducted during the summer of 2001 to determine the population of subyearling and yearling spring chinook in the Tucannon River. We estimated 44,618 subyearlings (BY 2000) and 397 yearlings (BY 1999) were present in the river. Evaluation staff also operated a downstream migrant trap. During the 2000/2001 emigration, we estimated that 8,157 (BY 1999) wild spring chinook smolts emigrated from the Tucannon River.

Monitoring survival rate differences between natural and hatchery reared salmon continues. Smolt-to-adult return rates (SAR) for natural salmon continue to average about five times higher than for hatchery salmon. However, hatchery salmon survive about five times greater than natural salmon from parent to adult progeny. Natural fish survival remains below the replacement level, while hatchery fish survival is nearly three times above it. Due to the low SAR for hatchery fish, the mitigation goal of 1,152 salmon of Tucannon River stock was not achieved.

## Program Objectives

Congress authorized implementation of the Lower Snake River Fish and Wildlife Compensation Plan (USACE 1975). As a result, Lyons Ferry Hatchery (LFH) was constructed and Tucannon Fish Hatchery (TFH) was modified. One objective of these hatcheries is to compensate for the estimated annual loss of 1,152 Tucannon River spring chinook salmon adults caused by hydroelectric projects on the Snake River. In 1984, Washington Department of Fish and Wildlife (WDFW) began to evaluate the success of these two hatcheries in meeting the mitigation goal, and identifying factors that would improve performance of the hatchery fish. The WDFW also initiated the Tucannon River Spring Chinook Captive Broodstock Program in 1997 that is currently funded by the Bonneville Power Administration (BPA). The project goal is to rear captive salmon selected from the supplementation program (1997-2001 BY's) to adults, rear their progeny, and release approximately 150,000 smolts annually into the Tucannon River between 2003-2007. These smolt releases, in combination with the current hatchery supplementation program (goal $=132,000$ smolts) and wild production, are expected to produce 600-700 returning adult spring chinook to the Tucannon River each year from 2005-2010. This report summarizes work performed by the WDFW Spring Chinook Evaluation Program from April, 2001 through April, 2002.

## Facility Descriptions

Lyons Ferry Hatchery is located on the Snake River (rkm 90) at its confluence with the Palouse River (Figure 1). It is used for adult broodstock holding and spawning, and early life incubation and rearing. All juvenile fish are marked and returned to TFH for acclimation. Tucannon Fish Hatchery, located at rkm 59 on the Tucannon River, has an adult collection trap on site (Figure 1). Juveniles rear at TFH through winter. In February, the fish are transported to Curl Lake Acclimation Pond (AP) and volitionally released. The yearly supplementation production goal is 132,000 fish for release as yearlings at $30 \mathrm{~g} /$ fish or 15 fish per pound (fpp). The captive brood production goal is 150,000 yearling smolts at $30 \mathrm{~g} /$ fish.

## Tucannon River Watershed Characteristics

The Tucannon River empties into the Snake River between Little Goose and Lower Monumental dams approximately 622 rkm from the mouth of the Columbia River (Figure 1). Stream elevation rises from 150 m at the mouth to $1,640 \mathrm{~m}$ at the headwaters (Bugert et al. 1990). Total watershed area is approximately $1,295 \mathrm{~km}^{2}$. Local habitat problems related to logging, road
building, recreation, and agriculture/livestock grazing have limited the production potential of spring chinook in the Tucannon River. Land use in the Tucannon watershed is approximately $37 \%$ cropland, $35 \%$ rangeland, and $27 \%$ forest (McCullough 1999). Five unique strata have been distinguished by predominant land use, habitat, and landmarks (Table 1).

Figure 1. Location of the Tucannon River, Lyons Ferry, and Tucannon hatcheries within the Snake River Basin.

Table 1. Description of five strata within the Tucannon River.

| Strata | Land Ownership/Usage | Spring Chinook Habitat | River Kilometer |
| :---: | :---: | :---: | :---: |
| Lower | Private/Agriculture \& Ranching | Not-Usable (temperature limited) | $0.0-20.1$ |
| Marengo | Private/Agriculture \& Ranching | Marginal (temperature limited) | $20.1-39.9$ |
| Hartsock | Private/Agriculture \& Ranching | Fair to Good | $39.9-55.5$ |
| HMA | State \& Forest Service/Recreational | Good/Excellent | $55.5-74.5$ |
| Wilderness | Forest Service/Recreational | Excellent | $74.5-86.3$ |

Program staff deployed 15 continuous recording thermographs throughout the Tucannon River to monitor daily minimum and maximum water temperatures (temperatures are recorded every 1 to 1.2 hours) from May through October. Data from each of these water temperature recorders are kept on an electronic file in our Dayton office. During 2001, maximum temperatures near the mouth (rkm 3) of the Tucannon River reached 80EF (26.7EC) on 3 different days. Maximum temperatures where spring chinook juveniles were rearing during the hottest part of the summer ranged from 60.7EF (15.9EC) in the upper HMA stratum (rkm 74.5) to 74.5EF (23.6EC) in the lower Hartsock stratum (rkm 43.3)(Figure 2).

The upper lethal temperature for chinook fry is 77.2 EF ( 25.1 EC ) while the preferred temperature range is $53.6-57.2 \mathrm{EF}$ ( $12-14 \mathrm{EC}$ ) (Scott and Crossman 1973). The optimum range of temperature in freshwater, which controls the rate of growth and survival of young, is 55.4-62.6EF (13-17EC) (Becker 1983). Theurer et al. (1985) estimated that spring chinook production in the Tucannon River would be zero for all stream reaches having maximum daily July water temperatures greater than 75 EF ( 23.9 EC ) (or average mean temperature of 68.0 EF (20EC)). Based on the preferred and optimum temperature limits, fish returning to the upper watershed have the best chance for survival, and recovery efforts should be maximized in this area (Figure 2).

It is hoped that recent initiatives to improve habitat within the Tucannon Basin, such as the Tucannon River Model Watershed Program, will: 1) restore and maintain natural stream stability; 2) reduce water temperatures; 3 ) reduce upland erosion and sediment delivery rates; and 4) improve and re-establish riparian vegetation. Theurer et al. (1985) estimated that improving riparian cover and channel morphology in the Tucannon River mainstem would increase chinook rearing capacity by a factor of 2.5 . Habitat restoration efforts should permit increased utilization of habitat by spring chinook salmon in the marginal sections of the middle reaches of the Tucannon River and increase fish survival.

Figure 2. Maximum temperature, average maximum temperature, and average minimum temperature recorded by thermographs at 15 selected sites along the Tucannon River, May-October, 2001.

## Adult Salmon Evaluation

## Broodstock Trapping

The annual collection goal for broodstock is 50 natural and 50 hatchery adults collected throughout the duration of the run. Additional jack salmon may also be collected to contribute to the broodstock if necessary. Jack contribution to the broodstock can be no more than their percentage in the overall run. Returning hatchery salmon were identified by lack of the adipose fin.

The TFH adult trap began operation in April with the first spring chinook captured May 9. The trap was operated through September. A total of 681 fish entered the trap ( 404 natural adults, 1 natural jack, 181 hatchery adults, and 95 hatchery jacks), and 106 were collected and hauled to LFH for broodstock (Table 2, Appendix A). Fish not collected for broodstock were passed upstream. Adults collected for broodstock were injected with erythromycin and oxytetracycline $(0.5 \mathrm{cc} / 4.5 \mathrm{~kg})$; jacks were given half dosages. Fish received formalin drip treatments during holding at 167 ppm every other day at LFH to control fungus.

Based on previous year returns, we anticipated catching unmarked Umatilla origin hatchery fish. We decided prior to broodstock trapping that scale samples would be collected from all unmarked fish for scale pattern analysis in the hope of identifying hatchery origin fish. Unmarked fish collected for broodstock were injected with a Passive Integrated Transponder (PIT) tag for individual identification. If scale analysis determined that a "wild" fish collected for broodstock was actually of hatchery origin, that fish would have been identified by its PIT tag number and killed. None of the fish collected for broodstock were determined to be of hatchery origin, however, two fish passed upstream were later found to have been hatchery origin based on scale pattern analysis.

Table 2. Numbers of spring chinook salmon captured, trap mortalities, fish collected for broodstock, or passed upstream to spawn naturally at the TFH trap from 1986-2001.

|  | Captured at Trap |  | Trap Mortality |  | Broodstock Collected |  | Passed Upstream |  |

| 2001 | 405 | 276 | 0 | 0 | 52 | 54 | 353 | 222 |

${ }^{\text {a }}$ Two males (one natural, one hatchery) captured were transported back downstream to spawn in the river.
${ }^{\mathrm{b}}$ Three hatchery males that were captured were transported back downstream to spawn in the river.
${ }^{\mathrm{c}} 17$ stray LV and ADLV fish were killed at the trap.

## Broodstock Mortality

None of the 106 salmon collected for broodstock died prior to spawning in 2001 (Table 3).
Table 3 shows that prespawning mortality in 2001 was comparable to the mortality documented since broodstock began being held at LFH in 1992. Higher mortality was experienced when fish were held at TFH (1985-1991).

| Year | Natural |  |  | \% of collected | Hatchery |  |  | \% of collected |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2000 | 0 | 0 | 0 | 0.0 | 1 | 2 | 0 | 3.7 |
| 2001 | 0 | 0 | 0 | 0.0 | 0 | 0 | 0 | 0.0 |

## Broodstock Spawning

Spawning at LFH occurred once a week from August 28 to September 18, with peak eggtake on September 11. A total of 184,127 eggs were collected (Table 4). Eggs were initially disinfected and water hardened for one hour in iodophor ( 100 ppm ). Fungus on the incubating eggs was controlled with formalin applied every-other day at $1,667 \mathrm{ppm}$ for 15 minutes. Mortality to eyeup was $1.2 \%$ with an additional $3.8 \%$ loss of sac-fry, which left 174,934 fish for production. This is above the program release goal of 132,000 smolts due to the lack of pre-spawning mortalities, older age class of spawners, and higher fecundity. A release of marked parr (approximately 21,000 ) will occur in the spring of 2002 to allow us to stay within our maximum allowed number of smolts released under our Section 10 Permit $(150,000)$.

To prevent any stray fish from contributing to the population, all coded wire tags (CWT) were read prior to spawning. One hatchery male did not have wire and was killed outright. Scales from unmarked fish were read prior to spawning to check for hatchery growth patterns. Carcasses were buried instead of being used for nutrient enhancement due to the detection of Infectious Hematopoietic Necrosis virus in the broodstock.

Table 4. Number of fish spawned, estimated egg collection, and egg mortality of Tucannon River spring chinook salmon at LFH in 2001.

|  | Natural |  |  | Hatchery |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Spawn Date | Male | Female | Eggs Taken | Male | Female | Eggs Taken |

| Egg Mortality |  |  | 1,199 |  |  | 1,026 |

a Denotes live spawned fish.
Eggs were also collected as part of the Tucannon River Captive Broodstock Program. One hundred thirty-seven females from the 1997 BY captive broodstock were mature in 2001. Of those, 125 were spawned ( 20 were partial spawned), four were green and killed outright, five were pre-spawn mortalities, and three were found dead in the pond (DIP). Eggtake was 233,894 eggs and egg survival was $69 \%$. Mean fecundity was 1,990 eggs/female, based on 105 fully spawned females.

Forty-four females were mature from the 1998 BY captive broodstock. Of those, 41 were spawned (two partial spawned), two were green and killed outright, and there was one DIP. Eggtake was 47,409 eggs with egg survival of $81 \%$. Mean fecundity, based on 39 fully spawned females, was 1,160 eggs/female.

From the total captive brood eggtake of 281,303 eggs, loss to eye-up was $29.0 \%$ leaving 199,758 live eggs. An additional 4,494 dead eggs/fry (2.3\%) were picked at ponding leaving 195,264 fish for rearing. This is above the program release goal of 150,000 smolts due to higher than expected survival of captive brood adults. A release of marked parr (approximately 21,000) will occur in the spring of 2002 to allow us to stay within our maximum allowed number of smolts released under our Section 10 Permit $(150,000)$. We will conduct captive brood adult outplants in the future to lower our eggtake and stay within our maximum allowed number of smolts released. The Tucannon River Captive Broodstock Program was funded through the BPA and results achieved to date are more thoroughly described in the annual Tucannon River Spring Chinook Captive Broodstock Report (Gallinat and Bumgarner 2002).

## Radio Tracking

One radio tagged fish that entered the Tucannon River was tracked in 2001 (Table 5; Appendix B). This fish was tagged by the University of Idaho at Bonneville Dam on April 19 and entered the Tucannon River on May 9. Migration speed after river entry, timing and movements upstream, and spawning success were documented.

Mean travel rate from the lower river to rkm 57 (about 1 kilometer below the Tucannon Hatchery) was $2.72 \mathrm{rkm} /$ day. This rate was similar to upstream migration rates documented in
previous years (Mendel et al. 1993; Bumgarner et al. 1997). This fish had also been PIT tagged at the Tucannon River smolt trap on April 22, 1999 at a length of 110 mm . Growth rate from time of original PIT tagging to radio tagging averaged $27.3 \mathrm{~mm} /$ month.

Table 5. Radio tagging and recovery data of spring chinook salmon from the Tucannon River in 2001 from the University of Idaho study.

| Channel/ Code | Tagging Information |  |  |  |  | Recovery Data |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Date | Origin | Sex | $\begin{gathered} \text { FL } \\ (\mathrm{cm}) \end{gathered}$ | $\begin{gathered} \text { VI } \\ \text { tag } \end{gathered}$ | Date | Sex | $\begin{gathered} \text { FL } \\ (\mathrm{cm}) \end{gathered}$ | Spawned |
| 12/73 | 4/19 | Wild | M | 76.5 | --- | 10/03 | M | --- | Yes |

Radio tagged fish $12 / 73$ was a wild male and spent most of the summer directly across from Blue Lake (rkm 57.4). It was observed spawning near that location and descended downstream before its decomposing carcass was recovered near Bridge 13 (rkm 48.8) (Figure 3). The radio receiver, which had been located at the adult trap, was downloaded and confirmed that this fish went up the ladder on September 9 and stayed at the trap entrance for twenty-three hours before it swam back downstream to the area that it had been holding. It is unknown why this fish did not enter the trap.

Figure 3. Movements of the radio tagged spring chinook salmon recovered in the Tucannon River, 2001 (based on data collected and presented in Appendix B of this report).

## Natural Spawning

Spawning ground surveys were conducted on the Tucannon River weekly from August 29 to October 3, 2001 to count redds and determine the temporal and spatial distribution of spawners. Two hundred ninety-eight redds were counted and 181 natural and 45 hatchery origin carcasses were recovered (Table 6). One hundred sixty-eight redds ( $56 \%$ of total) and 112 carcasses ( $50 \%$ of total) were found above the adult trap.

| Stratum | Rkm ${ }^{\text {a }}$ | Number of redds | Carcasses Recovered |  |
| :---: | :---: | :---: | :---: | :---: |

## Historical Trends

Since the program's inception in 1985, redd concentrations have shifted downstream. Also, redd densities (redds/km) have declined in recent years (Table 7) due to low returns and a greater emphasis on broodstock collection to keep the spring chinook population above extinction. Number of redds in 2001 increased $224 \%$ from 2000 levels and were the most recorded since surveys began in 1985

Table 7. Number of spring chinook salmon redds and redds/km (in parenthesis) by stratum and year, and the number and percent of redds above and below the TFH adult trap in the Tucannon River, 1985-2001.

| Year | Strata |  |  |  | Total Redds | TFH Adult Trap |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2001 | 24 (2.7) | 189 (9.9) | 84 (5.3) | 1 (0.2) | 298 | 168 | 56.4 | 130 | 43.6 |

Note: - indicates the river was not surveyed in that section during that year.

## Genetic Sampling

No electrophoretic samples were collected from spring chinook recovered in the river or from the hatchery during spawning in 2001. We collected 168 DNA samples from adult salmon (99 natural origin and 69 hatchery origin) and 236 samples from captive broodstock spawners. These samples have been sent to the WDFW genetics lab in Olympia for analysis.

## Age Composition, Length Comparisons, and Fecundity

One objective of the monitoring program is to track the age composition of each year's return. This allows us to annually compare ages of natural and hatchery reared fish, and to examine long-term trends and variability in the age structure. Overall, hatchery origin fish return at a younger age than natural origin fish (Figure 4). This difference is likely due to smolt size-atrelease (hatchery origin smolts are generally $25-30 \mathrm{~mm}$ greater in length than natural smolts).

Figure 4. Historical (1985-2000), and 2001 age composition for spring chinook in the Tucannon River.

Age at return during 2001 was not similar to historical data for natural origin fish. Natural returns had fewer 5 year old fish than what is typically observed. This may be attributed to desirable ocean conditions that contributed to higher survival of 4 year old fish. Hatchery fish were composed of more Age 3 and fewer Age 4 fish than historically observed. The increase in hatchery jacks may be due to the release of larger smolts in 2000.

Another comparison we conduct on returning adult natural and hatchery origin fish is the difference between mean post-eye to hypural-plate lengths. We reported in the past (Bumgarner et al. 1994) that hatchery fish were generally shorter than natural origin fish of the same age. For many of the early return years this appeared to be true (Figures 5, 6, 7, and 8). However, overall for all combined return years, there is no difference in mean length between natural and hatchery origin fish, even though they migrate as smolts at significantly different sizes (Bugert et al. 1990; Bugert et al. 1991).

Fecundities (number of eggs/female) of natural and hatchery origin fish from the Tucannon River program have been documented since 1990 (Table 8). A one-way analysis of variance was performed to determine if there were significant differences in mean fecundities at the $95 \%$
confidence level. Natural origin females had significantly higher fecundities than hatchery origin fish for both Age $4(\mathrm{P}<0.001)$ and 5 year old fish $(\mathrm{P}<0.001)$.

Mean size of natural origin eggs in Age 4 spring chinook from the Tucannon River averaged $0.224 \mathrm{~g} / \mathrm{egg}$ and hatchery origin eggs averaged $0.239 \mathrm{~g} / \mathrm{egg}$. This difference was statistically significant at the $95 \%$ confidence level ( $\mathrm{P}<0.05$ ). This may help explain why hatchery origin females are less fecund. Mean egg size in Age 5 salmon was $0.271 \mathrm{~g} / \mathrm{egg}$ for natural origin and $0.270 \mathrm{~g} / \mathrm{egg}$ for hatchery origin females, but the difference was not significant $(\mathrm{P}=0.92)$.

## Coded-Wire Tag Sampling

Broodstock collection, pre-spawn mortalities, and carcasses recovered from spawning ground surveys provide representatives of the annual run that can be sampled for CWT study groups (Table 9). Stray fish were predominately from the Umatilla River, Oregon and are discussed in more detail in a later section of this report. In 2001, based on the estimated escapement of fish to the river, we sampled approximately $34.0 \%$ of the run (Table 10).

Table 9. Coded-wire tag codes of hatchery salmon sampled at LFH and the Tucannon River, 2001.

| Carcasses sampled | 241 | 104 | 345 |

## Arrival and Spawn Timing Trends

Peak arrival and spawn timing have always been monitored to determine if the hatchery program has caused a shift (Table 11). Peak arrival dates were based on greatest number of fish trapped on a single day. Peak spawn in the hatchery was determined by the day when the most females were spawned. Peak spawning in the river was determined by the highest daily redd counts.

Peak arrival during 2001 was slightly earlier for natural and hatchery fish as compared to previous years, but within the expected range compared to peak arrival before hatchery influence (1986-1988). Peak spawning date of hatchery fish in 2001 was also slightly earlier than in previous years, although within the range found from previous years. The duration of active spawning in the Tucannon River was also similar to previous years.

Table 11. Peak dates of arrival of natural and hatchery salmon to the TFH adult trap and peak (date) and duration (number of days) for spawning in the hatchery and river, 1986-2001.

| Year | Peak Arrival at Trap |  | Spawning in Hatchery |  |  | Spawning in River |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2001 | 5/23 | 5/23 | 9/11 | 9/04 | 20 | 9/12 | 35 |

## Total Run-Size

In general, redd counts have been directly related to total run-size entering the Tucannon River and passage of adult salmon at the TFH adult trap (Bugert et al. 1991). For 2001, we used sex ratios from collected broodstock and sex ratio observations on the spawning grounds to estimate the number of fish/redd. The run-size estimate for 2001 was calculated by adding the estimated number of fish upstream of the TFH adult trap, the estimated fish below the weir based on an estimated fish/redd ratio, the number of pre-spawn mortalities below the weir, and the number of broodstock collected (Table 12). Total run-size for 2001 was estimated at 1,012 fish ( 892 adults and 120 jacks). The total run for jacks and adults by origin has been estimated since 1985 (Appendix C).

Table 12. Estimated spring chinook salmon run to the Tucannon River, 1985-2001.

| Year $^{\mathbf{b}}$ | Total <br> Redds | Fish/Redd <br> Ratio $^{\mathbf{a}}$ | Spawning fish <br> In the river | Broodstock <br> Collected | Pre-spawning <br> Mortalities | Total <br> Run-Size | Percent <br> Natural |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1985 | 189 | 2.85 | 539 | 22 | 0 | 561 | 100 |
| 1986 | 200 | 2.85 | 570 | 116 | 0 | 686 | 100 |
| 1987 | 185 | 2.85 | 527 | 101 | 0 | 628 | 100 |
| 1988 | 117 | 2.85 | 333 | 125 | 0 | 458 | 96 |
| 1989 | 106 | 2.85 | 302 | 169 | 0 | 471 | 77 |
| 1990 | 180 | 3.39 | 610 | 135 | 7 | 753 | 66 |
| 1991 | 90 | 4.33 | 390 | 130 | 8 | 528 | 49 |
| 1992 | 200 | 2.82 | 564 | 97 | 81 | 753 | 55 |
| 1993 | 192 | 2.27 | 436 | 97 | 56 | 589 | 54 |
| 1994 | 44 | 1.59 | 70 | 70 | 0 | 140 | 70 |
| 1995 | 5 | 2.20 | 11 | 43 | 0 | 54 | 39 |
| 1996 | 68 | 2.00 | 136 | 80 | 11 | 247 | 66 |
| 1997 | 73 | 2.00 | 146 | 97 | 45 | 351 | 46 |
| 1998 | 26 | 1.94 | 51 | 89 | 4 | 144 | 59 |
| 1999 | 41 | 2.60 | 107 | 136 | 2 | 245 | 1 |
| 2000 | 92 | 2.60 | 239 | 81 | 2 | 339 | 24 |
| 2001 | 298 | 3.00 | 894 | 106 | 12 | 1012 | 71 |

a From 1985-1989 the TFH trap was temporary, thereby underestimating total fish passed upstream of the trap. The 1985-1989 fish/redd ratios were calculated from the 1990-1993 average, excluding 1991 because of a large jack run.
b In 1994, 1995, 1998 and 1999, fish were not passed upstream, and in 1996 and 1997, high pre-spawning mortality occurred in fish passed above the trap, therefore; fish/redd ratio was based on the sex ratio of broodstock collected.

## Stray Salmon into the Tucannon River

Spring chinook from other river systems (strays) have periodically been recovered in the Tucannon River, though generally at a low proportion of the total run (Bumgarner et al. 2000). Through 1998 the incidence of stray spring chinook salmon was negligible (Table 13). However, in 1999, Umatilla River strays accounted for $8 \%$ of the total Tucannon River run, and that rate increased to $12 \%$ in 2000. The increase in the number of strays, particularly from the Umatilla River, is a concern since it exceeds the allowable 5\% stray rate of hatchery fish as deemed acceptable by National Marine Fisheries Service (NMFS). Beginning with the 1997 brood year releases, the Oregon Department of Fish and Wildlife (ODFW) and Confederated Tribes of the Umatilla Indian Reservation (CTUIR) ceased marking Umatilla River origin spring chinook with an RV or LV fin clip (65-70\% of releases). Because of this action, Age 4 fish that returned in 2001 were not distinguishable from wild origin spring chinook from the Tucannon River. For 2001, scale samples were collected from all wild fish collected for broodstock and passed upstream at the adult trap. None of the fish collected for broodstock were determined to be of hatchery origin, however, two fish passed upstream were later found to be of hatchery origin based on scale pattern analysis. Beginning with the 2000 BY, Umatilla River hatcheryorigin spring chinook will be $100 \%$ marked. This will help ensure that genetic integrity is maintained for ESA listed spring chinook in the Tucannon River.

${ }^{\text {a }}$ All CWT codes recovered from groups that were $100 \%$ marked were given a 1:1 expansion rate. Groups that were not $100 \%$ marked were expanded based on the percentage of unmarked fish. The expansion is based on the percent of stray carcasses to Tucannon River origin carcasses and the estimated total run in the river.

## Juvenile Salmon Evaluation

## Hatchery Rearing, Marking, and Release

## Hatchery Rearing and Marking

Based on recommendations by Gallinat et al. (2001), the adipose clip was abandoned for Tucannon River spring chinook to prevent this listed population from potential harvest in the sport fishery. All 2000 BY supplementation juveniles were marked with a right red elastomer and tagged with CWTs on October 11-18, 2001. Captive brood progeny juveniles (2000 BY) were marked with agency-only wire on October 18, 2001. After tagging, hatchery personnel transported 111,156 supplementation fish ( 33 fpp ) to TFH on October 25, 2001. A total of 3,074 captive brood progeny ( 14 fpp ) were transferred to TFH on November 5, 2001.

Length and weight samples were collected only twice on the 2000 BY fish during the rearing cycle due to an outbreak of Bacterial Kidney Disease (BKD). Handling the fish under such conditions to obtain the information was not considered wise. Samples collected on May 18 and again on February 19 found the captive brood progeny to be out-of-size (Table 14). This was likely due to overfeeding a small number of fish in one raceway. Hatchery managers were notified and feeding rates were adjusted.

| Brood/ <br> Date | Progeny Type | Sample Location | N | Mean Length | CV | K | FPP |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 |  |  |  |  |  |  |  |
| 5/18/01 | Supplementation | LFH | 227 | 87.6 | 7.3 | 1.15 | 58.2 |

| 5/18/01 | Captive Brood | LFH | 472 | 103.5 | 6.7 | 1.24 | 32.7 |
| 2/19/02 | Captive Brood | TFH | 160 | 163.5 | 10.8 | 1.13 | 8.9 |

## 2000 Brood Release

Captive brood progeny ( 3,055 BY00) were transported to Curl Lake AP on February 21, 2002. A total of 102,289 supplementation juveniles ( 2000 BY ) were transported to Curl Lake on February 22, 2002. The outlet of Curl Lake was opened for volitional release on March 15, and continued until April 23 when fish were forced out, with an estimated release of 102,099 supplementation fish and 3,055 captive brood progeny (Tables 15 and 16). Supplementation fish were at the release goal of 15 fish/lb. Insufficient samples of captive brood progeny were collected at Curl Lake for length and weight analysis, but they were already at 9 fish/lb in February. Due to their
large size difference and small number of captive brood progeny released, the 2000 BY captive brood progeny and supplementation fish were not PIT tagged for survival comparisons.

## Natural Parr Production

Program staff surveyed the Tucannon River at index sites in 2001 to estimate the density and population of subyearling (Table 17, Appendix D) and yearling spring chinook salmon. Snorkel surveys were conducted using a total count method (Griffith 1981, Schill and Griffith 1984). Population size was determined by multiplying the mean fish density (fish $/ 100 \mathrm{~m}^{2}$ ) by the estimated total area within each stratum. Twenty-five sites were snorkeled in 2001 (August 13 to August 15). Total area snorkeled was approximately $2.5 \%$ of the suitable rearing habitat in the Tucannon River. A total of 1,102 subyearling and 10 yearling spring chinook were counted during the surveys. We estimated that $44,618( \pm 12,809)$ subyearling and $397( \pm 281)$ yearling chinook were present in the river.

Table 17. Number of sites, area snorkeled, population estimates, and $95 \%$ confidence intervals for subyearling and yearling spring chinook within the Tucannon River, 2001.

| Lower | -- | -- | -- | -- | -- | Cstimate |

## Natural Smolt Production

Program staff operated a 5 ft rotary screw trap nearly continuously at rkm 3 on the Tucannon River from October 16, 2000 to June 30, 2001 to estimate numbers of migrating natural and hatchery spring chinook. The smolt trap was pulled for three days during the trapping season ( $10 / 21 / 00,10 / 29 / 00$, and $2 / 06 / 01$ ). Other data on natural and hatchery spring chinook smolts such as peak outmigration, lengths of smolts, descaling, etc., have not been reported here for simplicity. Those data are available upon request.

We examined the influence of specific abiotic variables on spring chinook emigration during the last four trapping seasons (1997/1998 to 2000/2001) using correlation analysis. Significant relationships were found between the total number of wild spring chinook smolts captured $\left(\log _{10}\right.$ transformed for normality) emigrating from the Tucannon River and flow (ft $\left.{ }^{3} / \mathrm{sec}\right)\left(\mathrm{r}^{2}=0.08, \mathrm{P}<\right.$ $0.01)$, staff gauge level ( $\mathrm{r}^{2}=0.10, \mathrm{P}<0.01$ ), time of year ( $\mathrm{r}^{2}=0.08, \mathrm{P}<0.01$ ), and water temperature ( $\mathrm{r}^{2}=0.01, \mathrm{P}<0.07$ ). Although these variables are statistically significant, they account for only a small amount of the variability in the number of emigrating fish. This is understandable as smoltification is a physiological process and the resulting outmigration may only be slightly influenced by abiotic factors. No statistically significant relationships were found between the number of emigrating wild spring chinook smolts and secchi disk reading (turbidity indicator).

Similarly, no significant relationships were found between the total number of hatchery spring chinook smolts captured ( $\log _{10}$ transformed) and flow, staff gauge level, time of year (week number), water temperature, or secchi disk reading. There was a statistically significant relationship at the $90 \%$ level between the number of hatchery spring chinook smolts captured and water temperature ( $\mathrm{r}^{2}=0.30, \mathrm{P}<0.10$ ).

Each week we attempted to determine trap efficiency by clipping a portion of the caudal fin on a few representative captured migrants and releasing them about one kilometer upstream. The percent of marked fish recaptured was used as an estimate of weekly trapping efficiency. To calculate trapping efficiency during weeks when low numbers of fish were caught we examined the relationship between trap efficiency and the variables flow, staff gauge, number of fish captured, water temperature, and time of year (week). There were no statistically significant relationships between trap efficiency for wild spring chinook and any of the variables examined. The only statistically significant relationship found between trap efficiency for hatchery spring chinook and any of the variables examined was staff gauge level ( $\mathrm{r}^{2}=0.30, \mathrm{P}<0.10$ ). Despite the low statistical power, we believe that trap efficiency decreases as flow increases.

Flow is the dominant factor affecting downstream migrant trapping operations in any system according to Seiler et al. (1999). Groot and Margolis (1991) state that the rate of downstream migration of chinook fingerlings appears to be both time and size dependent and may also be related to river discharge and the location of fish in the river. They state that during years of low and stable river flow, the rate of downstream migration was negatively correlated with discharge, whereas, when flows were higher and more variable, the rate of migration was positively correlated with discharge.

Mean daily flow data was provided by the U.S.G.S. gauge at Starbuck, WA (rkm 12.7). Correlation analysis indicated a statistically significant relationship between flow and the staff gauge level at the smolt trap at the $99 \%$ confidence level $\left(\mathrm{r}^{2}=0.95\right)$. As the U.S.G.S. flow data is computer monitored on a continuous basis, is in relatively close proximity to the smolt trap, and there was a strong statistically significant relationship between the variables, we estimated trap efficiencies with the following equations:

## Wild Spring Chinook

Trap Efficiency $=29.932$ - 0.037 (Flow)
$\underline{\text { Hatchery Spring Chinook }}$
Trap Efficiency $=24.994-0.046$ (Flow)

To estimate potential juvenile migrants passing when the trap was not operated, such as periods when freshets washed out large amounts of debris from the river, we calculated the average number of fish trapped for three days before and three days after non-trapping periods. The mean number of fish trapped daily was then divided by the estimated trap efficiency to calculate fish passage. The estimated number of fish passing each day was then applied to each day the trap was not operated.

We estimated that 8,157 , or $51.2 \%$ of the 1999 BY parr estimates, passed the smolt trap during 2000-2001. (Table 18). We also estimated that $56 \%$ of the hatchery fish released from Curl Lake Acclimation Pond (1999 BY) passed the smolt trap. Tucannon Fish Hatchery personnel noted the occurrence of hatchery spring chinook on May 4, 2001 in Rainbow Lake (rkm 59.2), one of eight public fishing lakes within the WDFW W.T. Wooten Wildlife Area. A water intake screen at the lake inlet adjacent to the Tucannon River experienced a structural problem which resulted in the entrainment of some spring chinook smolts into the lake. Due to the potential recreational harvest impacts on this listed stock, the fishery was closed on May 10, 2001. Efforts to facilitate the voluntary out-migration and a salvage operation at the lake for recovery and release were conducted and the lake was re-opened to fishing on June 30, 2001.

Table 18. Monthly and total population estimates, with $95 \%$ confidence intervals, for natural and hatchery origin emigrants from the Tucannon River, 2001.

a Percent survival to smolt based on estimated number of parr from summer snorkel surveys (natural origin) or from TFH release numbers (hatchery origin).

## Juvenile Migration Studies

In 2001, WDFW used PIT tags to study the emigration timing and success of wild and hatchery origin spring chinook. The tags allowed us to identify the characteristics of successful smolts. We tagged 158 wild and 301 hatchery origin spring chinook over a four week period (Table 19). No fish were killed during PIT tagging, though it is likely some delayed mortality occurred after release. Detection rates were higher for wild chinook and mean travel days were generally higher for hatchery spring chinook. Detection rates may be higher for wild chinook because they are smaller (25-48 mm less) and more likely to be captured at collection facilities, or their survival was actually slightly higher.

Note: Mean travel times listed are from the total number of fish detected at each dam, not just unique recoveries for a tag code. Abbreviations are as follows: LMJ-Lower Monumental Dam, MCJ- McNary Dam, JDJ-John Day Dam, BONN-Bonneville Dam, TD- Mean Travel Days.

## Survival Rates

Point estimates of population sizes have been calculated for various life stages (Table 20 and 21) of natural origin fish from spawning ground and juvenile mid-summer population surveys, smolt trapping, and fecundity estimates. From these two tables, survivals between life stages have been calculated for both natural and hatchery salmon to assist in the evaluation of the hatchery program. These survival estimates provide insight as to where efforts should be directed to improve not only the survival of fish produced within the hatchery, but fish in the river as well.

As expected, juvenile (egg-fry-smolt) survival rates for hatchery fish are considerably higher than for naturally reared salmon (Table 22) because they have been protected in the hatchery. However, smolt-to-adult return rates (SAR) of natural salmon were about five times higher than for hatchery reared salmon (Table 23 and 24). The mean hatchery SAR's ( $0.18 \%$ ) documented from the 1985-1996 broods were below the goal SAR of $0.87 \%$ established under the LSRCP. Hatchery SAR's for Tucannon River salmon need substantial improvement if we ever hope to meet the mitigation goal of 1,152 salmon.

Table 20. Estimates of natural Tucannon spring chinook salmon abundance by life stage for 1985-2001 broods.

a 1985 and 1989 mean fecundity of natural females is average of 1986-88 and 1990-93, 1999 mean fecundity of natural fish is the based on the mean of 1986-1998 .
b Numbers do not include down river harvest estimates or out of basin recoveries.
c Number of smolts is less than actual release number. 57,316 parr were released in October 1993, with an estimated 7\% survival. Total number of hatchery fish released from the 1992 brood year was 140,725 . We therefore use the listed number of 87,752 as the number of smolts released.

We found a significant relationship between survival calculated from CWT returns through the Regional Mark Information System (RMIS) database and size of smolts at release, with larger fish (6-10 fish/lb) having higher survival ( $\mathrm{r}^{2}=29.3, \mathrm{P}<0.01$ ) (Table 25; Appendix E). However, years in which smaller fish (14-19 fish/lb) were released also coincided with poor ocean conditions, drought years, and flood events within the Tucannon River watershed. Decreasing the release size of smolts has allowed hatchery fish to more closely resemble wild fish and decrease the incidence of precocious fish and returning jacks, but overall survival appears to have decreased. An experimental release of fish at $15 / \mathrm{lb}$ and $10 / \mathrm{lb}$ during the same year would provide a direct comparison of differences in survival, age structure, length, and fecundity of adult returns.

Table 25. Estimated survival for selected sizes at release (fpp) based on a fitted square root correlation model of individual coded wire tag (CWT) recoveries of hatchery fish from the RMIS database (1985-1996 brood year releases).

| Size at Release <br> (FPP) | Predicted Survival | 95\% Confidence Limits | 95\% Prediction Limits |
| :---: | :---: | :---: | :---: |
| 6.0 | 0.27 | $0.18-0.37$ | $0.03-0.73$ |

| 36.0 | 0.01 | $0.00-0.07$ | $0.00-0.21$ |

While SAR's were lower for hatchery salmon, overall survival of hatchery salmon to return as adults was higher than naturally reared fish because of the early-life survival advantage provided by the hatchery (Table 22). With the exception of the 1988 and 1997 brood years, naturally produced fish remain below the replacement level (Figure 9; Table 26). Based on adult returns from the 1985-1997 broods, naturally reared salmon produced 0.9 adults for every spawner, while hatchery reared fish produced 2.5 adults.

Figure 9. Return per spawner ratio (with replacement line) for the 1985-1997 brood years.

Table 26. Parent-to-progeny survival estimates of Tucannon River spring chinook salmon from 1985 through 1997 brood years (1997 incomplete).

## Fishery Contribution

An original goal of the LSRCP supplementation program was to enhance wild (natural) returns of salmon to the Tucannon River by providing 1,152 hatchery reared fish to the system. Such an increase would allow for limited harvest of the stock and increased spawning. Unfortunately, hatchery adult returns have been below the program goal. Moreover, natural escapement, with the exception of the 2001 run, has further declined (Figure 10). Based on 1985-1996 brood year CWT recoveries from the RMIS database (Appendix E), harvest has accounted for approximately $5.5 \%$ of the hatchery adult fish recovered annually and accounted for as high as $40 \%$ of the returns for one brood year based on a small number of recoveries. While exploitation has been relatively low, fishing mortality is one form of mortality fisheries managers can control. Adipose clipped hatchery fish have traditionally been targeted in the sport fishery. This hatchery fin clip was abandoned for Tucannon River spring chinook starting with the 2000 brood year to mitigate fishing mortality on this ESA listed population. Supplementation fish are now marked with a CWT and a red visible implant elastomer tag behind the right eye. Captive brood progeny are marked only with agency-only wire tags to distinguish them from supplementation origin fish. Out-of-basin stray rates of Tucannon River spring chinook have been low (Appendix E), with an average of $3.8 \%$ of the adult hatchery fish straying to other river systems/hatcheries for brood years 1985-1996 (range 0-20\%).

Figure 10. Total escapement for Tucannon River spring chinook salmon for the 1985-2001 run years.

## Conclusions and Recommendations

Washington's LSRCP hatchery spring chinook salmon program has failed to return adequate numbers of adults to meet the mitigation goal of the program. The program has failed because SARs of hatchery origin fish have consistently been below the assumed SAR of hatchery smolts as described under the LSRCP, even though hatchery returns have generally been at 2-3 times the replacement level. Further, the natural population of spring chinook salmon in the river has declined and remained below the replacement level for most years, with the majority (95\%) of the mortality occurring between the green egg and smolt stages. Mortality within the migration corridor has also contributed to the decline. The end result has been a slow but steady replacement of the natural population with the hatchery stock. While this neither was, nor is the desired result of the hatchery program, in many ways the hatchery program has helped conserve the natural population within the river by returning enough adults to allow some spawning in the river. System survivals (in-river, ocean) must increase in the future for the program to reach its full potential, and the spring chinook run be returned to historical levels.

Until that time, the evaluation program will continue to document and study life history survivals, genotypic and phenotypic traits, and examine procedures within the hatchery that can be improved to benefit the program. Based on our previous studies and current data involving survival and physical characteristics we recommend the following:

1. Monitoring of water temperatures in the Tucannon River has expanded with assistance from the local Conservation District with more emphasis being placed on instream and riparian restoration work within the river. These water temperature data series will continue to document the physical environment of the river as it changes over time. The desired change (cooling of the river) will likely benefit the natural spring chinook population in the river.

Recommendation: Continue to assist the local Conservation District with long term monitoring of water temperatures in the Tucannon River. Within the next 5 years, provide a complete summary of water temperature data collected from the Tucannon River since program inception.
2. We continue to see annual differences in phenotypic characteristics of returning salmon (i.e., hatchery fish are generally younger in age and less fecund than natural origin fish), yet other traits such as run and spawn time have changed little over the program's history. Further, genetic analysis to date indicates little difference between the natural and hatchery populations.

Recommendation: Continue to collect as many carcasses as possible for the most accurate age composition data. Continue to assist hatchery staff with picking eyed eggs to obtain fecundity estimates for each spawned female. Continue to collect other biological data (lengths, run
timing, spawn timing, DNA samples, juvenile parr production, smolt trapping, and life stage survival) to continue the documentation of effects (positive or negative) that the hatchery program may have on the natural population.
3. Documenting the success of hatchery origin fish spawning in the river has become an increasingly frequent topic among managers within the Snake River Basin and with National Marine Fisheries Service. Little, if any, data to date exists on this subject. With the hatchery population in the Tucannon River slowly replacing the natural population, we are offered an opportunity to study the effects of the hatchery spawners in the natural environment.

Recommendation: Participate in a reproductive success study for spring chinook being developed jointly by NMFS/WDFW personnel. Continue to use snorkel surveys during the summer months to estimate spring chinook parr production in the river. Examine the relationship between redd counts and the following years parr production, smolt numbers and returning adults in context of the proportion of hatchery spawners in the river.
4. The new adult trap was installed in 1998 around the TFH water intake dam. In 1998 and 1999, no fish were intentionally passed above the trap for natural spawning in the river. However, each year redds and fish have been found during spawning ground surveys. An estimator for the number of fish that bypass the trap each year is needed to allow managers to estimate the total run to the river more accurately.

Recommendation: Mark (opercle punch) all fish captured and released at the TFH adult trap. Document the number of recaptures in the trap during the season to document fall back rate. Examine all carcasses recovered above the trap during spawning and carcass surveys for marks to estimate trapping efficiency.
5. Subbasin and recovery planning for listed species in the Tucannon River will identify factors limiting the spring chinook population and strategies to recover the population. Development of a recovery goal for the population would be helpful to develop and evaluate strategies for habitat, hydropower, harvest and hatcheries.

Recommendation: Assist subbasin planning in the development of a recovery goal for spring chinook in the Tucannon River.
6. Smolt and adult detection capabilities for PIT tagged salmon within the Columbia and Snake River basins is becoming more widespread. These capabilities can help estimate survival rates for release groups to aid in evaluation of program success.

Recommendation: Utilize the SURPH2 PIT tag model software and present summaries of juvenile survival rates in future reports. Collect interrogation data on adult detections to estimate SAR. Increase sample size of PIT tags if necessary, and document stray Tucannon fish above lower Granite Dam.

## Appendix B

## Movements of the radio tagged spring chinook recovered in the Tucannon River, 2001

| Appendix B. Movements of the radio tagged spring chinook recovered in the Tucannon River, 2001. The fish was tagged and released by the University of Idaho at Bonneville Dam. Abbreviations used: pp = pinpoint, to locate fish within 10-20 m of stream side, CG = campground, $\mathbf{C O L}=$ Columbia River, HMA = \#'s refer to snorkel index sites, $\mathbf{S N R}=$ Snake River, $\mathbf{R k m}=$ river kilometer, $\mathbf{R B}, \mathbf{L B}=$ right bank, left bank |  |  |  |
| :---: | :---: | :---: | :---: |
| Chan/ Code Date | Tuc Rkm | Location | Comments |
| 12/73 |  |  |  |
| 4/19 | COL | Bonneville Dam | Tagged (natural male, 76.5 cm ) |
| 5/09 | 3.0 | Smolt Trap | Fixed Site |
| 5/10 | 9.5 | Fletcher's Bridge |  |
| 5/15 | 31.0 | Broughton's/Tucannon Rd. |  |
| 5/18 | 37.0 | Hovrud's Silt Basin |  |
| 5/22 | 47.4 | Above Bridge 12 | pp , in large pool |
| 5/24 | 54.9 | HMA Headquarter's; Below C.G. 1 |  |
| 5/29 | 57.4 | Across from Blue Lake | Set up receiver at Hatchery Intake |
| 6/21 | 57.4 | Across from Blue Lake |  |
| 7/06 | 57.4 | Across from Blue Lake | pp under log near pool |
| 8/15 | 57.4 | Across from Blue Lake |  |
| 9/05 | 57.4 | Across from Blue Lake |  |
| 9/09 | 59.0 | Hatchery Intake | Fixed Site, fish stayed at trap entrance 23 hrs . |
| 9/10 | 59.0 | Hatchery Intake | Fixed Site |
| 9/17 | 57.4 | Across from Blue Lake |  |
| 9/20 | 57.4 | Across from Blue Lake |  |
| 9/25 | 57.4 | Across from Blue Lake | pp |
| 10/03 | 48.8 | 100 meters above Bridge 13 | Recovered tag, fish spawned; natural male |

## Appendix C

## Estimated Total Run-Size of Tucannon River Spring Chinook Salmon (1985-2001)

Appendix C. Total estimated run-size of spring chinook salmon to the Tucannon River, 1985-2001.

| Run <br> Year | Wild <br> Jacks | Wild <br> Adults | Total <br> Wild | Hatchery <br> Jacks | Hatchery <br> Adults | Total <br> Hatchery | Total <br> Run-Size |

 This program receives Federal financial assistance from the U.S. Fish and Wildlife Service. It is the policy of the Washington State Department of Fish and Wildlife (WDFW) to adhere to the following: Title VI of the Civil Rights Act of 1964, Section 504 of the Rehabilitation Act of 1973, Title II of the Americans with Disabilities Act of 1990, the Age Discrimination Act of 1975, and Title IX of the Education Amendments of 1972. The U.S. Department of the Interior and its bureaus prohibit discrimination on the bases of race, color, national origin, age, disability and sex (in educational programs). If you believe that you have been discriminated against in any program, activity, or facility, please contact the WDFW ADA Coordinator at 600 Capitol Way North, Olympia, Washington 98501-1091 or write to:
